# Proposal for Using DAФNE as Linac Pulse Stretcher for the Positron Beam 

S. Guiducci<br>ICFA Mini-Workshop on DAFNE as Open Accelerator Test Facility in year 2020 December 17 ${ }^{\text {th }}, 2018$

## A positron beam for Dark sector experiments

- An application of the DAФNE test-beam facility for Dark sector experiments, using the positron ring as a Linac Pulse Stretcher (LPS) to distribute the positrons of a single linac pulse in a much longer pulse, is proposed
- The PADME experiment is at present taking data at the BTF beam-line searching for the dark photon ( $A^{\prime}$ ) in the $\mathrm{e}^{+} \mathrm{e}^{-} \rightarrow \mathrm{A}^{\prime} \gamma$ process in a positron-on-target experiment
- The DAФNE linac can provide a number of positrons as high as $10^{10}$ /pulse in a 200 ns long pulse
- In order to keep the pile-up probability in the calorimeter at an acceptable level, the number of positrons for PADME is limited below $10^{5} /$ pulse
- The low duty-factor $\left(10^{-5}=200 \mathrm{~ns} / 20 \mathrm{~ms}\right)$ is a major limitation for the PADME experiment at BTF
- However, by injecting the beam in the DAФNE positron ring and by spilling it with a slow resonant extraction the duty factor can be increased by 3 orders of magnitude ( $\sim 1 \%=0.2 \mathrm{~ms} / 20 \mathrm{~ms}$ )
- All the following considerations are based on the work done at LNF for the ALFA proposal:
S. Guiducci, G. Martinelli, M. Preger, LNF-78/22(R), 22 maggio 1978
and IEEE Trans. On Nucl. Sci., Vol. NS-26, No.3, June 1979

## Layout of the DAФNE injection system

- The linac beam will be injected directly into the DAФNE ring without passing through the accumulator
- This will require a modification of the transfer line in order to bend the beam directly in the DAФNE hall (as it was done for ADONE)

## Resonant Extraction in a nutshell

- With a value of the betatron tune near to the $1 / 3$ rd resonance and a proper setup of sextupoles the stability region in the horizontal phase space ( $x, x^{\prime}$ ) is delimited by a triangle
- Particles outside the borders of the triangle become unstable and move outward along three lines, which are the continuation of the triangle's sides
- After injecting the beam inside the triangle it is possible, by moving the betatron tune toward the resonance, to extract all particles at a given time reducing the size of the triangle
- We will adopt a monochromatic extraction: the chromaticity will be adjusted in such a way that as far as the particles lose energy by synchrotron radiation their tune gets closer to the resonance and they are extracted

## Schematic layout of the beam horizontal phase space at the extraction septum

- The injected beam has a hollow shape
- Particles outside the stability triangle start moving on the extraction directions and the jump $\Delta x$ between two successive passages increases going outward
- The coordinates of the triangle's upper vertices are:

$$
x_{1,2}= \pm \rho \sqrt{\frac{\beta_{x}^{e x t}}{R}} \frac{\Delta v_{x}}{2 \sqrt{3} H_{33}} \quad ; \quad x_{1,2}^{\prime}=\rho \sqrt{\frac{1}{\beta_{x}^{\text {ext }} R}} \frac{\Delta v_{x}}{6 H_{33}}
$$

with $R=$ ring radius and $\rho=$ average bending radius, $H_{33}$ depends on the betatron phases and on the integrated strengths of the sextupoles along the ring, $\Delta v_{x}$ is the betatron tune distance from the resonance

## Some Comments

- Analytic expressions to evaluate the extraction time and the extracted beam parameters (emittance and energy spread) are reported in LNF-78/22(R)
- These formulae, valid for a symmetric lattice with the extraction septum placed in the symmetry point, assume that $m / 3$ is the only resonant term driving the particle trajectories
- They have been used to give a preliminary estimate of the extraction parameters
- To achieve a more precise estimate on the extracted beam parameters a study based on particle tracking is needed

[^0]
## DAФNE Lattice modifications

- The machine is made symmetric with respect to the centers of the LONG and SHORT straight sections: the 2 IRs are both equal to IR2, with non intersecting beams
- Sextupoles are kept in the present positions
- The injection septum is kept in the present position
- The extraction septum is in the IR1 straight section, on the outside of the ring, where there is space for the extraction line
- $\beta_{x}$ at the extraction septum has to be the ring maximum, the function $\alpha_{x}$ and the dispersion function $D_{x}$ need to be zero to minimize the extracted beam emittance
- The horizontal tune is near to the $1 / 3$ resonance

## Optical functions in half ring

## 

LPS ring from mid2

\text { (SXT OFF) }
\end{gathered}
$$

$C_{x}=-3.3, C_{y}=-6.26$
(k2.sf = $13.8 ; k 2 . s d=-8.6$ )
inj. septum

## Tracking at the injection septum

Selection of the optimum beta at the end of the transfer line

Injection septum

$$
\beta_{x}=14 \mathrm{~m}
$$

Center of injected beam ellipse $x_{0}=2.45 \mathrm{~cm}$

## Tracking at fixed energy, no SR losses, no RF

## Tracking near the extraction energy, SR losses, no RF

Mad8 tracking with initial energy $\Delta \mathrm{P} / \mathrm{P}=-0.0045$, average radiation energy loss (no fluctuations), RF off,

Extraction septum $x=4 \mathrm{~cm}$
Collimators $x=4.5 \mathrm{~cm}$ collimators included

## Extracted beam parameters

- All particles with initial $\Delta p / p=-0.0045$ are extracted at the septum within 90 turns
- Total area of the extracted beam in the phase space is:

$$
W_{r}=8 \cdot 10^{-7} \mathrm{~m} \cdot \mathrm{rad}
$$

- Total extracted relative momentum spread is:

$$
\Delta p / p_{\mathrm{ext}}=1.4 \times 10^{-3}
$$

- If injected beam has a momentum spread $+.0055>\Delta p / p>-0.0045$ the extraction time (time needed for particles with $\Delta p / p=+0.0055$ to lose energy down to -0.0045 ) is: 570 turns +90 turns

$$
T_{\text {ext }}=660 \text { turns }=0.2 \mathrm{~ms}
$$

- Time between injections: $20 \mathrm{~ms} \rightarrow$ duty factor is $\mathbf{1 \%}$

## Needed hardware modifications

1. Remove the low- $\beta$ insertion from IR1
2. Magnetic extraction septum (can be equal to the injection one)
3. Electrostatic extraction septum
```
~ 50KV/cm, thickness ~100 \mum, length ~ 1m
```

4. Modification of the transfer line to inject directly from the linac to the ring
5. Insert a collimation system on the transfer line to control emittance and energy spread of the injected beam
6. Installation of additional shielding (to be evaluated)

## Conclusions

- A proposal to explore the possibility to use the DAФNE positron ring as a Linac pulse stretcher for the PADME experiment was presented
- The ring can be operated with RF cavity and wigglers OFF saving power consumption
- A preliminary estimate gives a duty factor of a factor 1000 larger than the one with the BTF beam, with an emittance below $1 \mathrm{~mm} \cdot \mathrm{mrad}$ and a momentum spread of a few per mil
- To give a more precise estimate of the extracted beam parameters detailed studies of all the error sources and of the required beam diagnostics are needed
