

Expression of Interest for a very long baseline neutrino oscillation experiment (LBNO)

André Rubbia (ETH Zurich)

nuTURN2012 - Neutrino at the Turning Point

May 10th, 2012

A decade after CHOOZ: the θ_{13} revolution

- T2K (Jun 2011):
 $\sin^2 2\theta_{13} = 0.03 - 0.34$ (90% CL).

T2K Collaboration, Phys.Rev.Lett. 107 (2011) 041801

- MINOS (July 2011):
 $\sin^2 2\theta_{13} \neq 0$ at 89% CL.

MINOS Collaboration, Phys.Rev.Lett. 107 (2011) 181802

- Double CHOOZ (Dec 2011):
 $\sin^2 2\theta_{13} = 0.017 - 0.16$ (90% CL).

Double CHOOZ Collaboration, arXiv: 1112.6353 [hep-ex].

- **Daya Bay** (Mar 2012):
 $\sin^2 2\theta_{13} \neq 0$ at 5.2σ (!),
 best-fit = 0.092.

Daya Bay Collaboration, arXiv: 1203.1669 [hep-ex].

- Reno (April 2012):
 exclude no oscillations at 4.9σ

Reno Collab, arXiv:1204.0626v2

See talk by GL Fogli

$$\sin^2 (2\theta_{13}) = 0.092 \pm 0.016(stat) \pm 0.005(syst)$$

$$\sin^2 2\theta_{13} = 0.113 \pm 0.013(stat) \pm 0.019(syst)$$

The knowns and unknowns...

$$\sin^2 \theta_{12} = 0.312^{+0.017}_{-0.015}$$

$$\Delta m_{12}^2 = (7.59^{+0.20}_{-0.18}) \times 10^{-5} \text{ eV}^2$$

$$\sin^2 \theta_{23} = \begin{array}{l} 0.51 \pm 0.06 \\ 0.52 \pm 0.06 \end{array}$$

$$\Delta m_{31}^2 = \begin{array}{l} 2.45 \pm 0.09 \\ -(2.34^{+0.10}_{-0.09}) \end{array} \times 10^{-3} \text{ eV}^2$$

Solar

parameters
SK, SNO, Kamland

Atmospheric

parameters
SK, K2K, MINOS, T2K

→ *Mass ordering is hierarchical or inverted ?*

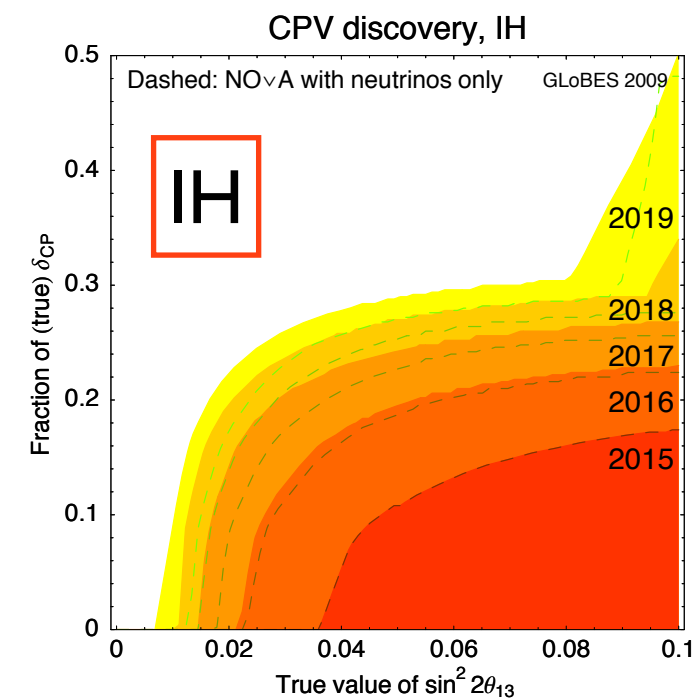

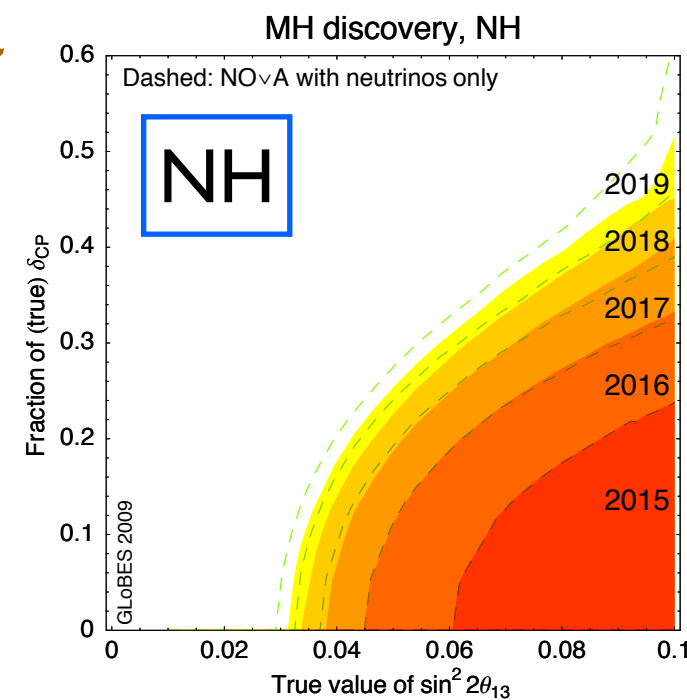

$$\sin^2 (2\theta_{13}) \simeq 0.09 \pm 0.02$$

$\delta_{CP} = [0, 2\pi]$ → *Complex phase is unknown. Because of similarities with CKM matrix, it is natural to expect a CP violation in the lepton sector. But what is the size of the effect ??*

T2K and NOvA: in the future

MH 90%C.L. sensitivity **CPV**

- Preliminary estimation of sensitivity of T2K and NOvA *See talk by Schwetz*
- Nominal beam power scenarios (750kW). Need to check beam power assumptions.
- For $\sin^2 2\theta_{13}=0.1$, approximately (at 90%C.L.):
 - MH: $\approx 50\%$ coverage
 - CPV: $\approx 30-40\%$ coverage (robustness vs MH ?)
- Is 90% C.L. enough ? at 3σ C.L. sensitivity is highly reduced even with largely increased statistics.
- Atmospheric neutrinos to the rescue ?
- Official curves to be produced by experiments with revised projections.

Huber et al., JHEP 0911:044,2009

not official

Ultimate physics goal - the next decade

- We cannot be satisfied with just setting limits.
- Neutrino oscillations data now indicate that significant CP-violation could occur in the leptonic sector.
- Need to address the **unsolved puzzle of the matter-antimatter asymmetry of the Universe** in a satisfactory way, by finding new sources of CPV and possibly baryon number violation
 - ★ **We must determine the neutrino mass hierarchy, measure δ_{CP} and determine the existence of CPV**
 - ★ **We must search for proton decay to test GUT**

A new massive neutrino observatory for long baseline neutrino studies, expandable to cover full CPV parameter space, and located deep underground, capable of proton decay searches

Oscillation phenomenology

Approximate formula (M. Freund) quadratic dep. on θ_{13} matter effect $\sim E$

$$P(\nu_\mu \rightarrow \nu_e) \approx \sin^2 \theta_{23} \frac{\sin^2 2\theta_{13}}{(\hat{A} - 1)^2} \sin^2((\hat{A} - 1)\Delta) \quad \begin{array}{l} \sim 7500 \text{ km} \\ \text{magic bln} \end{array}$$

CPV term quadratic dep. on θ_{13} matter effect $\sim E$

$$+ \alpha \frac{8J_{CP}}{\hat{A}(1 - \hat{A})} \sin(\Delta) \sin(\hat{A}\Delta) \sin((1 - \hat{A})\Delta) \quad \begin{array}{l} \sim 2540 \text{ km} \\ \text{magic bln} \end{array}$$

approximate dependence quadratic dep. on θ_{13} matter effect $\sim E$

$$+ \alpha \frac{8I_{CP}}{\hat{A}(1 - \hat{A})} \cos(\Delta) \sin(\hat{A}\Delta) \sin((1 - \hat{A})\Delta) \quad \begin{array}{l} \text{solar} \\ \text{term} \end{array}$$

$\sim L/E$ quadratic dep. on θ_{13} matter effect $\sim E$

$$+ \alpha^2 \frac{\cos^2 \theta_{23} \sin^2 2\theta_{12}}{\hat{A}^2} \sin^2(\hat{A}\Delta) \quad \begin{array}{l} \text{solar} \\ \text{term} \end{array}$$

linear dep. on θ_{13}

$$J_{CP} = 1/8 \sin \delta_{CP} \cos \theta_{13} \sin 2\theta_{12} \sin 2\theta_{13} \sin 2\theta_{23}$$

$$I_{CP} = 1/8 \cos \delta_{CP} \cos \theta_{13} \sin 2\theta_{12} \sin 2\theta_{13} \sin 2\theta_{23}$$

$$\alpha = \Delta m_{21}^2 / \Delta m_{31}^2, \quad \Delta = \Delta m_{31}^2 L / 4E$$

$$\hat{A} = 2VE / \Delta m_{31}^2 \approx (E_\nu / \text{GeV}) / 11 \text{ For Earth's crust.}$$

CP asymmetry grows as θ_{13} becomes smaller !

Correlations !

CP and Matter Asymmetries

★ CP-asymmetry in vacuum:

$$\mathcal{A}_{CP}^{vac}(\delta_{CP}) \equiv abs \left(\frac{P^{vac}(\nu) - P^{vac}(\bar{\nu})}{P^{vac}(\nu) + P^{vac}(\bar{\nu})} \right)$$

★ Asymmetry due to matter effects:

$$\mathcal{A}_{CP}(\rho) \equiv abs \left(\frac{P^{mat}(\nu) - P^{mat}(\bar{\nu})}{P^{mat}(\nu) + P^{mat}(\bar{\nu})} \right)$$

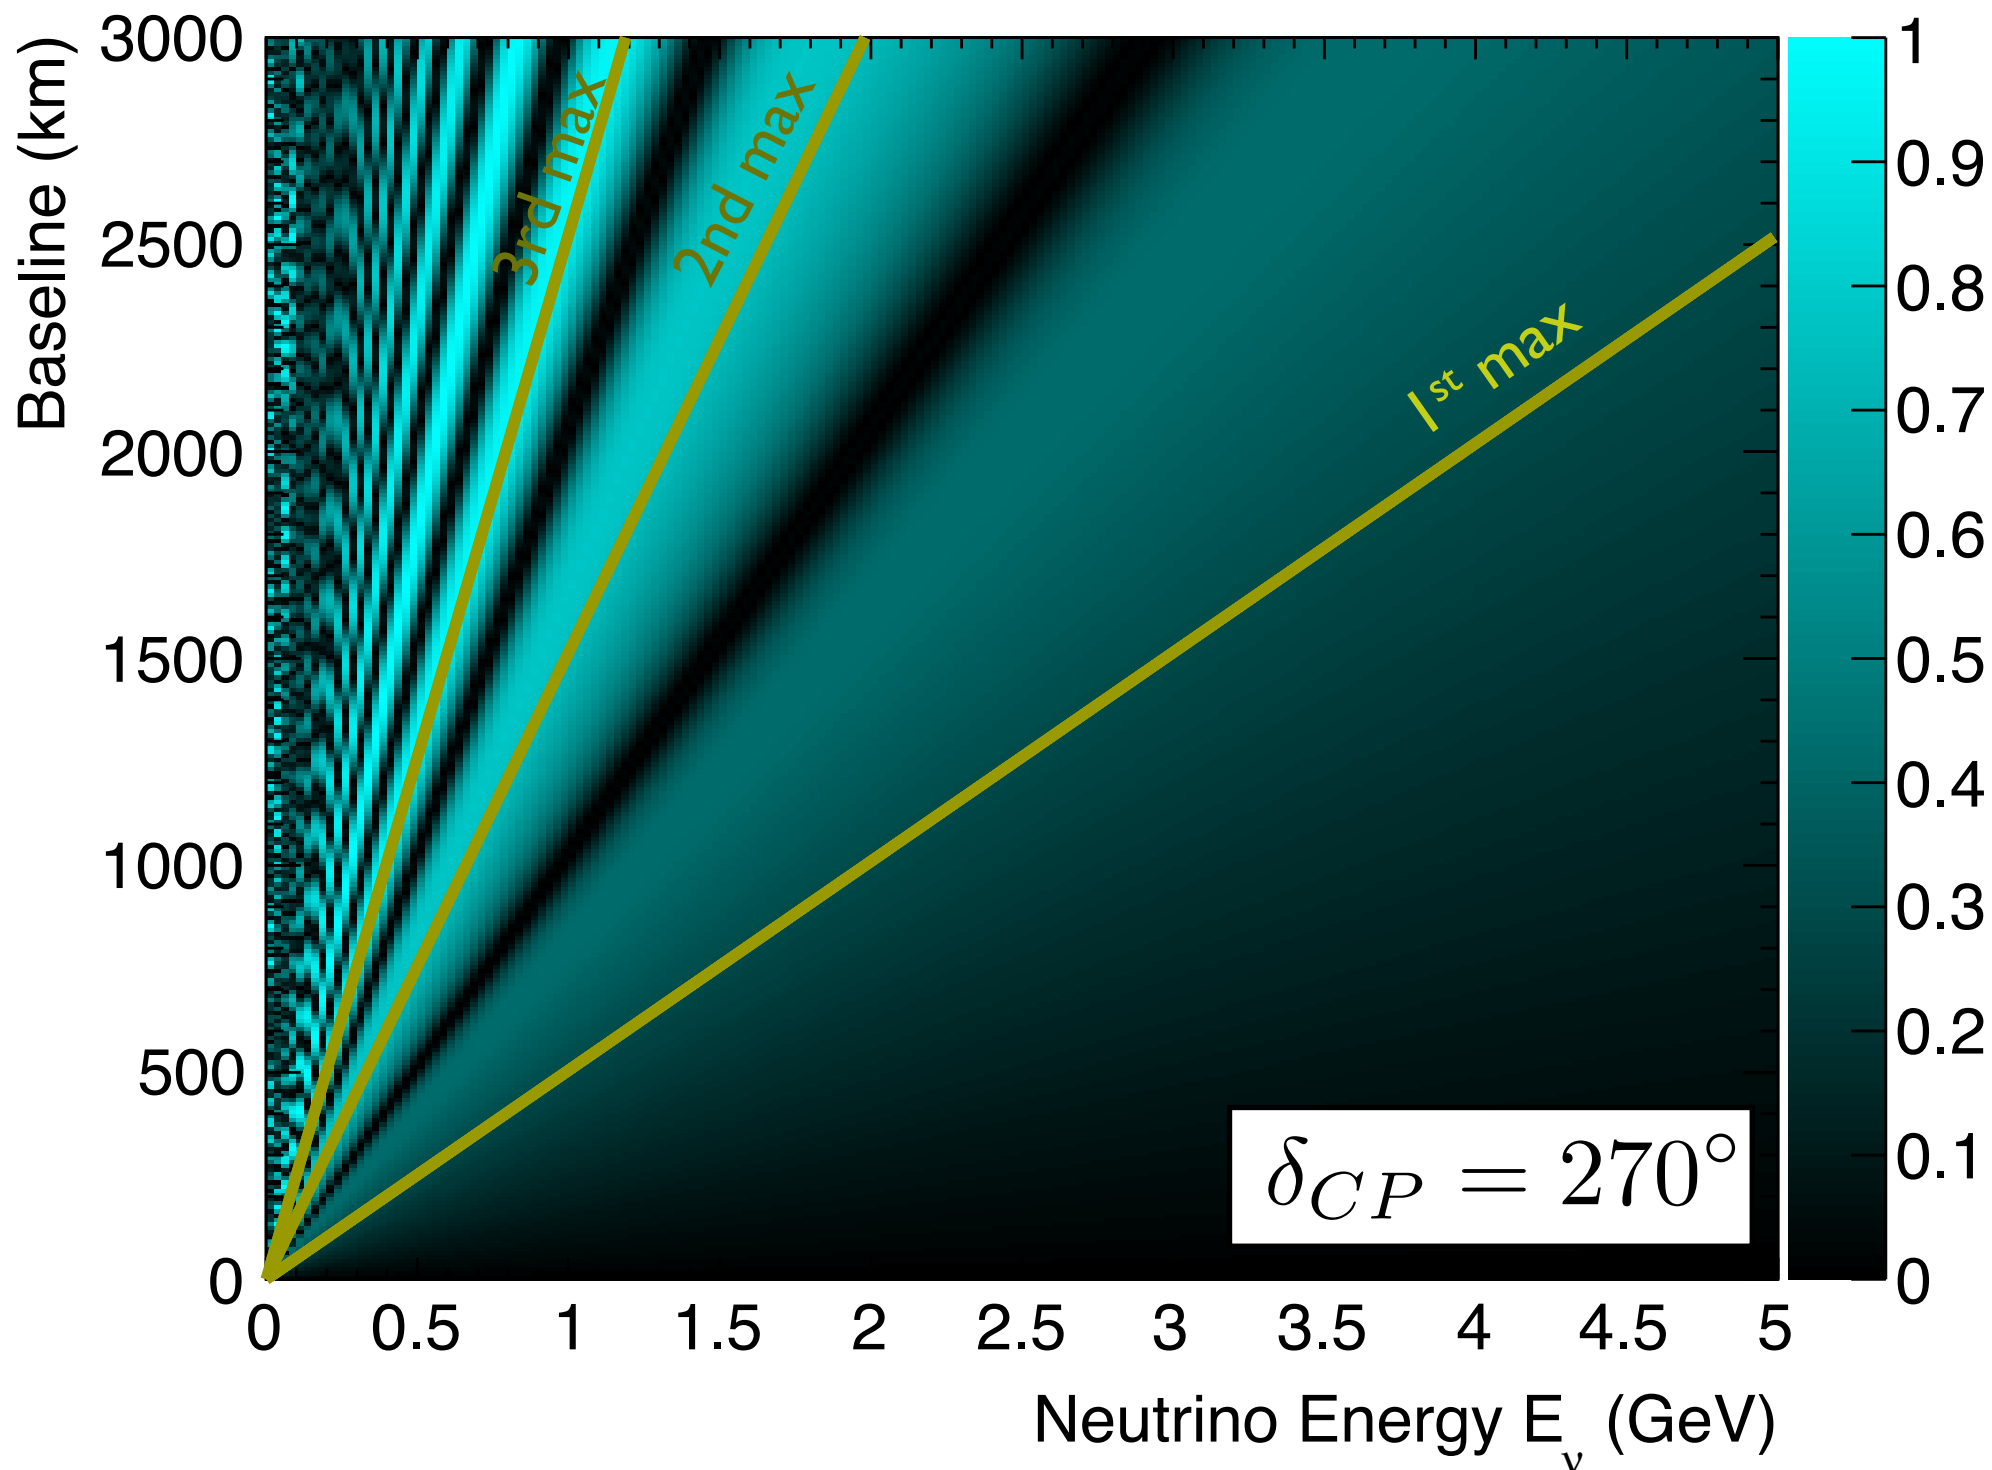

- CP asymmetries are largest at the 2nd, 3rd, ... maxima.
- Matter asymmetry dominates around the 1st maximum.
- Long(er) baselines, wide-band beams to cover several maxima are needed to resolve degeneracies.
- Experimentally: $E_{\nu}^{2nd\ max} \gtrsim 0.5\ \text{GeV} \implies L \gtrsim 1000\ \text{km}$

CP-violation determination (CPV)

$$\mathcal{A}_{CP}^{vac}(\delta_{CP}) \equiv \text{abs} \left(\frac{P^{vac}(\nu) - P^{vac}(\bar{\nu})}{P^{vac}(\nu) + P^{vac}(\bar{\nu})} \right)$$

$$\sin^2(2\theta_{13}) = 0.09$$

Normal mass hierarchy

Mass hierarchy determination (MH)

$$A_{CP}(\rho) \equiv \text{abs} \left(\frac{P^{mat}(\nu) - P^{mat}(\bar{\nu})}{P^{mat}(\nu) + P^{mat}(\bar{\nu})} \right)$$

$$\sin^2(2\theta_{13}) = 0.09$$

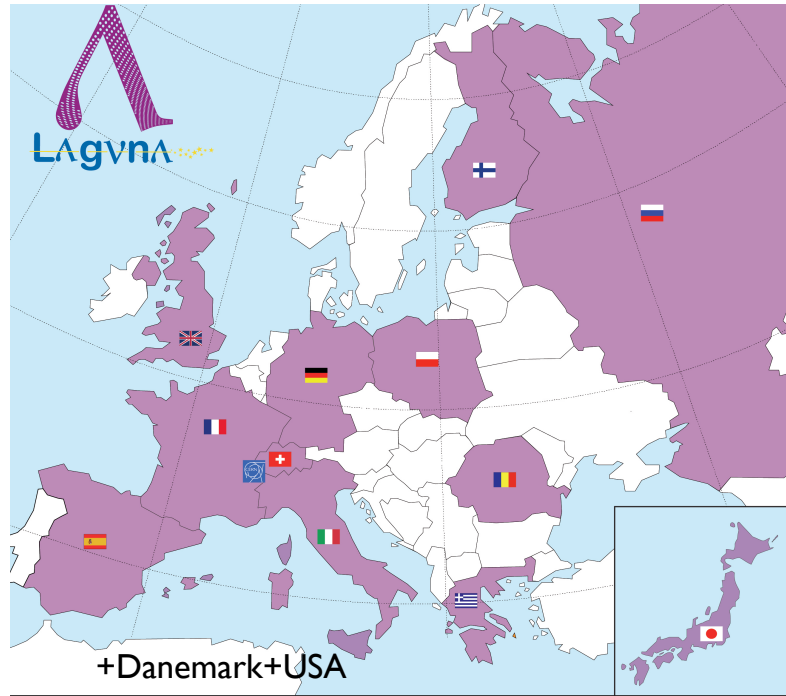

Normal mass hierarchy

CERN

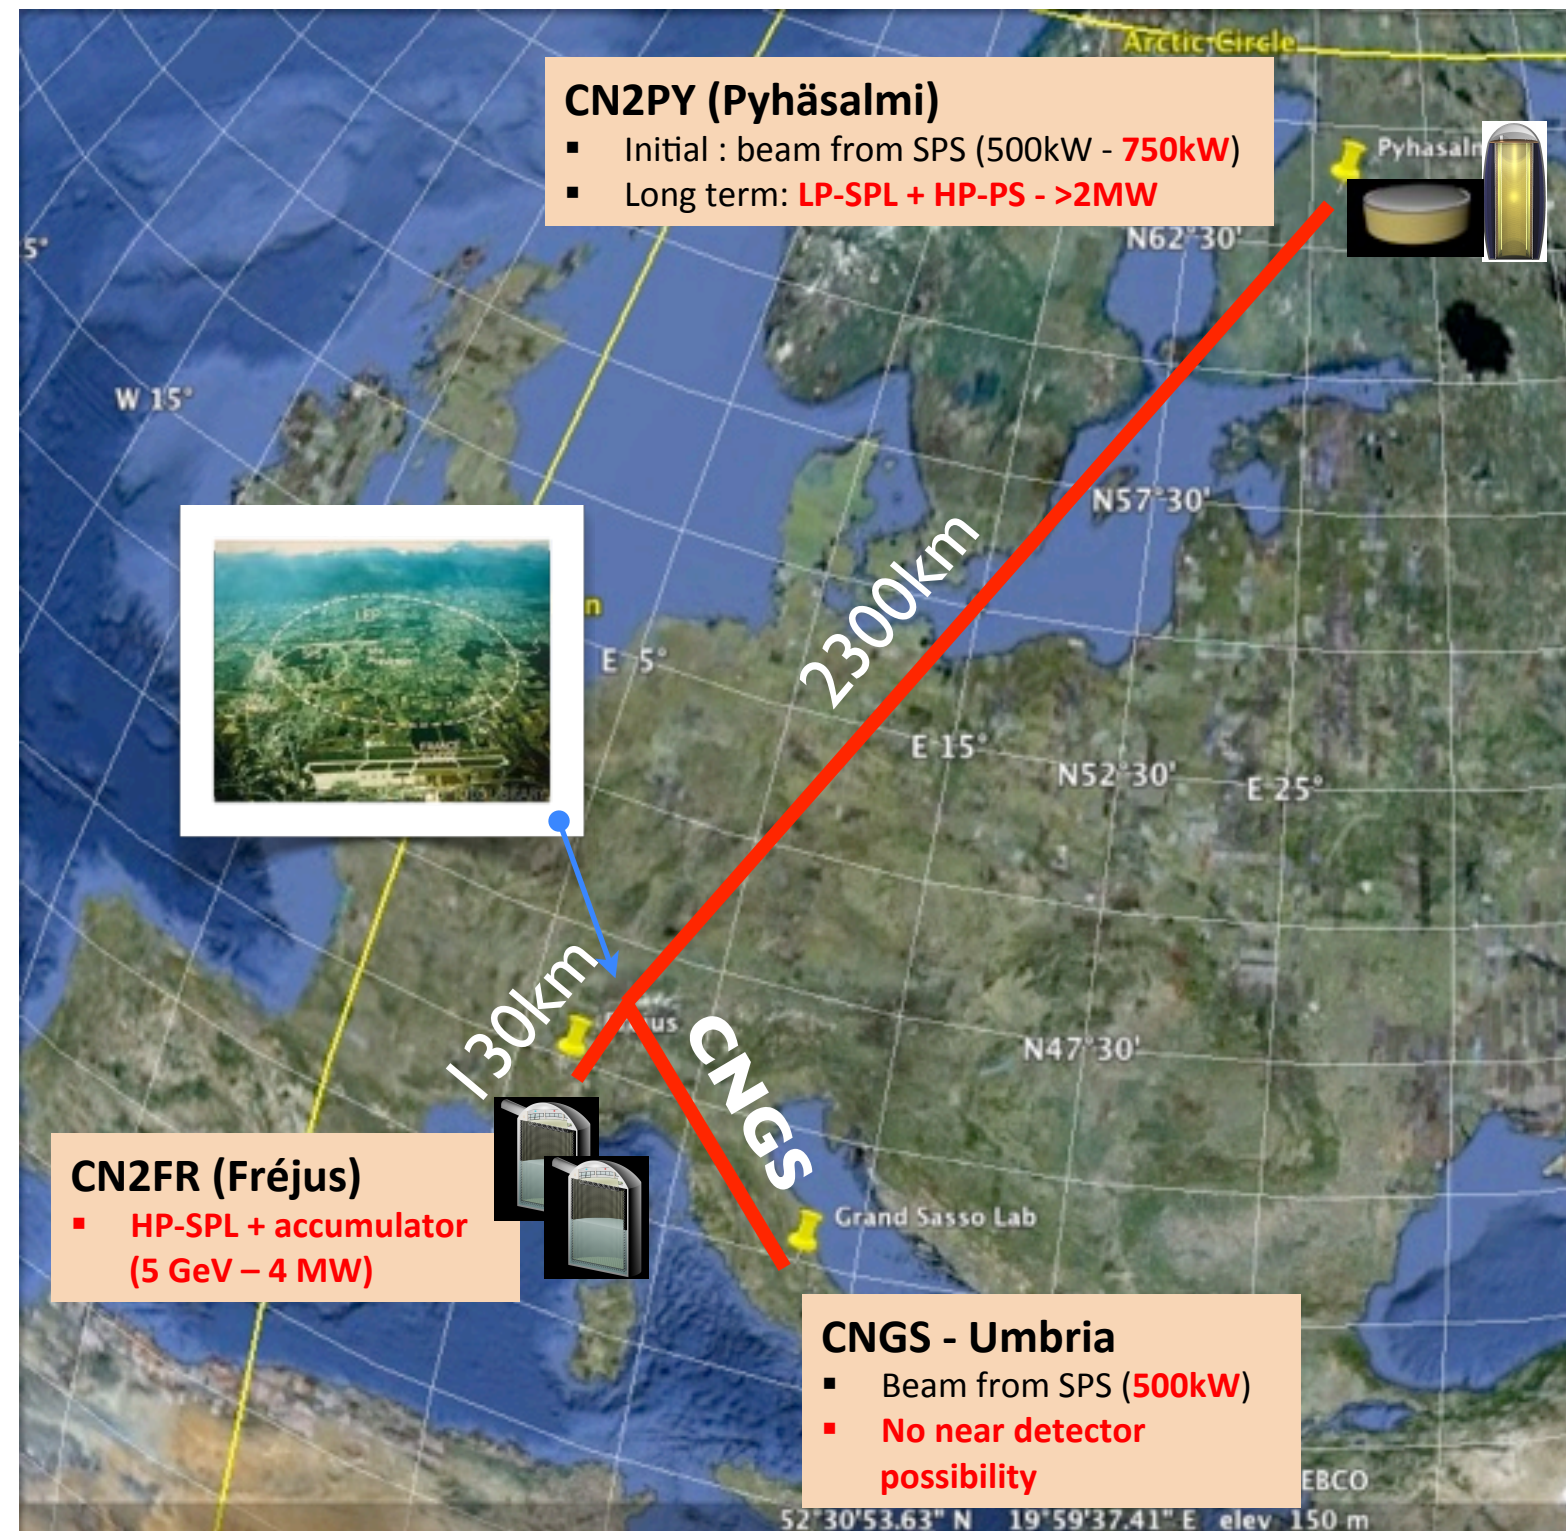

European sites: LAGUNA-LBNO

arXiv:1003.1921 [hep-ph]

Three far sites considered in details

- ▶ **Large Water Cerenkov Detector.** CERN-Fréjus is a short baseline. It offers good synergy for enhanced physics reach with β -beam at $\gamma=100$
- ▶ **Liquid Argon TPC & magnetized iron + Liquid Scintillator detectors** CERN-Pyhäsalmi is the longest baseline. It offers good synergy for enhanced physics reach with a NF
- ▶ [CNGS is an existing beam but is considered at lower priority (missing near detector, limited power upgrade scenarios)]

Pyhäsalmi site location

See talk by T Enqvist

- ▶ CUPP : Centre for Underground Physics in Pyhäsalmi (www.cupp.fi)
- ▶ Location: $63^{\circ} 39' 31''\text{N} - 26^{\circ} 02' 48''\text{E}$
- ▶ Distances (by roads)
 - ▶ Oulu – 165 km
 - ▶ Jyväskylä – 180 km
 - ▶ Helsinki – 450 km
- ▶ Distance to CERN 2300 km
- ▶ Good traffic connections
 - ▶ the main highway: Helsinki – Jyväskylä – Oulu – ...
 - ▶ the second busiest airport in Oulu
 - ▶ rail yard at the mine
- ▶ Inhabitants: ~ 6000

Present state of mine

Present: The Pyhäsalmi mine (Inmet Mining Ltd., Canada)

- ▶ Produces Cu, Zn, and FeS₂
- ▶ The deepest mine in Europe
 - ▶ Depths down to 1400 m (4000 m.w.e.) possible
- ▶ The most efficient mine of its size and type
- ▶ Very modern infrastructure
 - ▶ lift (of 21.5 tons of ore or 20 persons) down to 1400 metres takes ~3 minutes
 - ▶ via 11-km long decline it takes ~40 minutes (by truck)
 - ▶ good communication systems
- ▶ Operation time still 7–8 years with currently known ore reserves (presumably until 2018)
- ▶ Compact mine, small 'foot print'
 - ▶ water pumping and other maintenance works not major issues

Some unique features of Pyhäsalmi

- ▶ **Many optimal conditions satisfied simultaneously:**
 - ▶ Infrastructure in **perfect state** because of current exploitation of the mine
 - ▶ **Unique assets available** (shafts, decline, services, sufficient ventilation, water pumping station, pipes for liquids, underground repair shop...)
 - ▶ **Very little environmental water**
 - ▶ Could be **dedicated to science activities** after the mine exploitation ends (around 2018)
- ▶ One of the deepest location in Europe (4000 m.w.e.)
- ▶ The distance from CERN (2300 km) offers unique long baseline opportunities.
- ▶ The site has the lowest reactor neutrino background in Europe, important for the observation of very low energy MeV neutrinos.

 500'000 m³ excavation

Neutrinos from CERN to Pyhäsalmi

[arXiv:hep-ph/0305042v1](https://arxiv.org/abs/hep-ph/0305042v1)

- Distance CERN-Pyhäsalmi = 2288 km
- Deepest point = 103.8 km
- Abundant geophysical data about crust and upper mantle available
- Densities = $2.4 \div 3.4 \text{ g/cm}^3$
- Remaining uncertainty has small effect on neutrino oscillations

CERN-Pyhäsalmi: oscillations

★ Normal mass hierarchy

L=2300 km

$$\sin^2(2\theta_{13}) = 0.09$$

CERN-Pyhäsalmi: oscillations

★ Inverted mass hierarchy

L=2300 km

$$\sin^2(2\theta_{13}) = 0.09$$

LBNO Eol: the priors

- A significantly better sensitivity than the (combined) T2K and NOvA, with an improved method to conclusively determine mass ordering and to explore CP-violation \Rightarrow **exploit L/E dependence with WBB at long baseline \Rightarrow spectral information provides unambiguous oscillation parameters sensitivity.**
- A detector with better signal efficiency and better background rejection than T2K & NOvA but with a mass of the same order as T2K/SuperK & NOvA \rightarrow **>20 kton very fine sampling tracking detector**
- There are compelling ν -astrophysics measurements and nucleon decay searches to be performed \rightarrow **deep underground location**
- A conventional wide band beam at an energy above 500 MeV is technically achievable and affordable, and enables at long baseline to study L/E dependence of oscillation probability with 1st & 2nd maxima \rightarrow **new conventional beam aimed at a baseline >1000 km**
- Large sensitivity to mass hierarchy with 100% coverage at $>5\sigma$ and the presently available beam power requires a very long baseline \rightarrow **baseline >1500 km**
- At a distance suitable for the NF for long term \rightarrow **baseline >2000 km.**

LBNO EoI: the rationale

- The adequacy and choice of the far location are based on several years of extensive and detailed site studies performed within the LAGUNA and LAGUNA-LBNO design studies. The LAGUNA-Pyhäsalmi project is well advanced and on track.
- The choice of Pyhäsalmi/FI recognizes that the features of the infrastructure at the deepest mine in Europe allowing underground access to -1400 m, and a baseline of 2300 km from CERN, **fulfill all priors**, and **offer unique technical advantages and physics opportunities not found or easily replicated elsewhere**.
- The EoI considers as an initial step a **new conventional neutrino beam** from CERN aimed at an **20 kton double phase LAr LEM TPC** (GLACIER) and a **magnetized iron detector** (MIND).
 - LAr LEM TPC offers new look and increased physics reach in many physics channels with a mass comparable to SuperK and NOvA.
 - The magnetized detector with muon momentum and charge determination collects an independent neutrino sample, and serves as a tail catcher for events occurring in the LAr.
 - The Pyhäsalmi site allows virtually limitless excavation possibilities hence target mass expansion until the ultimate “megaton” scale envisioned by LAGUNA.
- **This project, called LBNO, is the first priority of the LAGUNA-LBNO consortium and is endorsed by the NF community.**

LBNO EoI: the physics reach

- Initial setup 20 kton LAr LEM TPC + MIND + CERN SPS 700kW upgrade
- **Ultimate** long baseline oscillations measurements:
 - LBNO can measure all transitions (e/ μ /tau) and determine precisely oscillation parameters. It can achieve a **5 σ C.L. determination of the neutrino mass hierarchy** in a few years. In a 10 years run, it explores a **significant part of the CPV parameter space, namely 60% CPV coverage at 90%C.L.**
 - Both the local situation and the distance make it such that it can evolve into larger detector(s) and a more powerful beams (e.g HP-PS and/or NF) and thus, **offers a long term vision**. For example, with a three-fold increase in exposure, **it reaches 75% CPV coverage at 3 σ C.L.** Competitive with T2HK (even more with JPARC MR at 700kW...) and LBNE.
- **Strongly** extended sensitivity to nucleon decay in several channels. E.g. some channels with sensitivity similar to HK:
$$Br(p \rightarrow \bar{\nu} K) > 2 \times 10^{34} y (90\% C.L.) \quad Br(n \rightarrow e^- K^+) > 2 \times 10^{34} y (90\% C.L.)$$
- **Interesting** astrophysics: LBNO acts as an nu-observatory in the 10 MeV-100 GeV range. **5600 atmospheric events/yr** **relic SN, WIMP annihilation, ...**
>10000's events @ SN explosion@10kpc

Far detectors for long baseline

- **Double phase LAr LEM TPC (GLACIER): best detector for electron appearance measurements with excellent energy resolution and small systematic errors**
 - ▶ Exclusive final states, low energy threshold on all particles
 - ▶ Excellent ν energy resolution and reconstruction ability from sub GeV to a few GeV, from single prong to high multiplicity
 - ➔ Suitable for spectrum measurement with needed wide energy coverage
 - ▶ Excellent π^0 /electron discrimination
 - ➔ Wide band On-Axis beam is tolerable
- **Magnetized Muon Detector (MIND): conventional and well-proven detector for muon CC, and NC**
 - ▶ muon momentum & charge determination, inclusive total neutrino energy
 - ▶ compatible with NF

New LBNO neutrino beam

See talk by I Efthymiopoulos

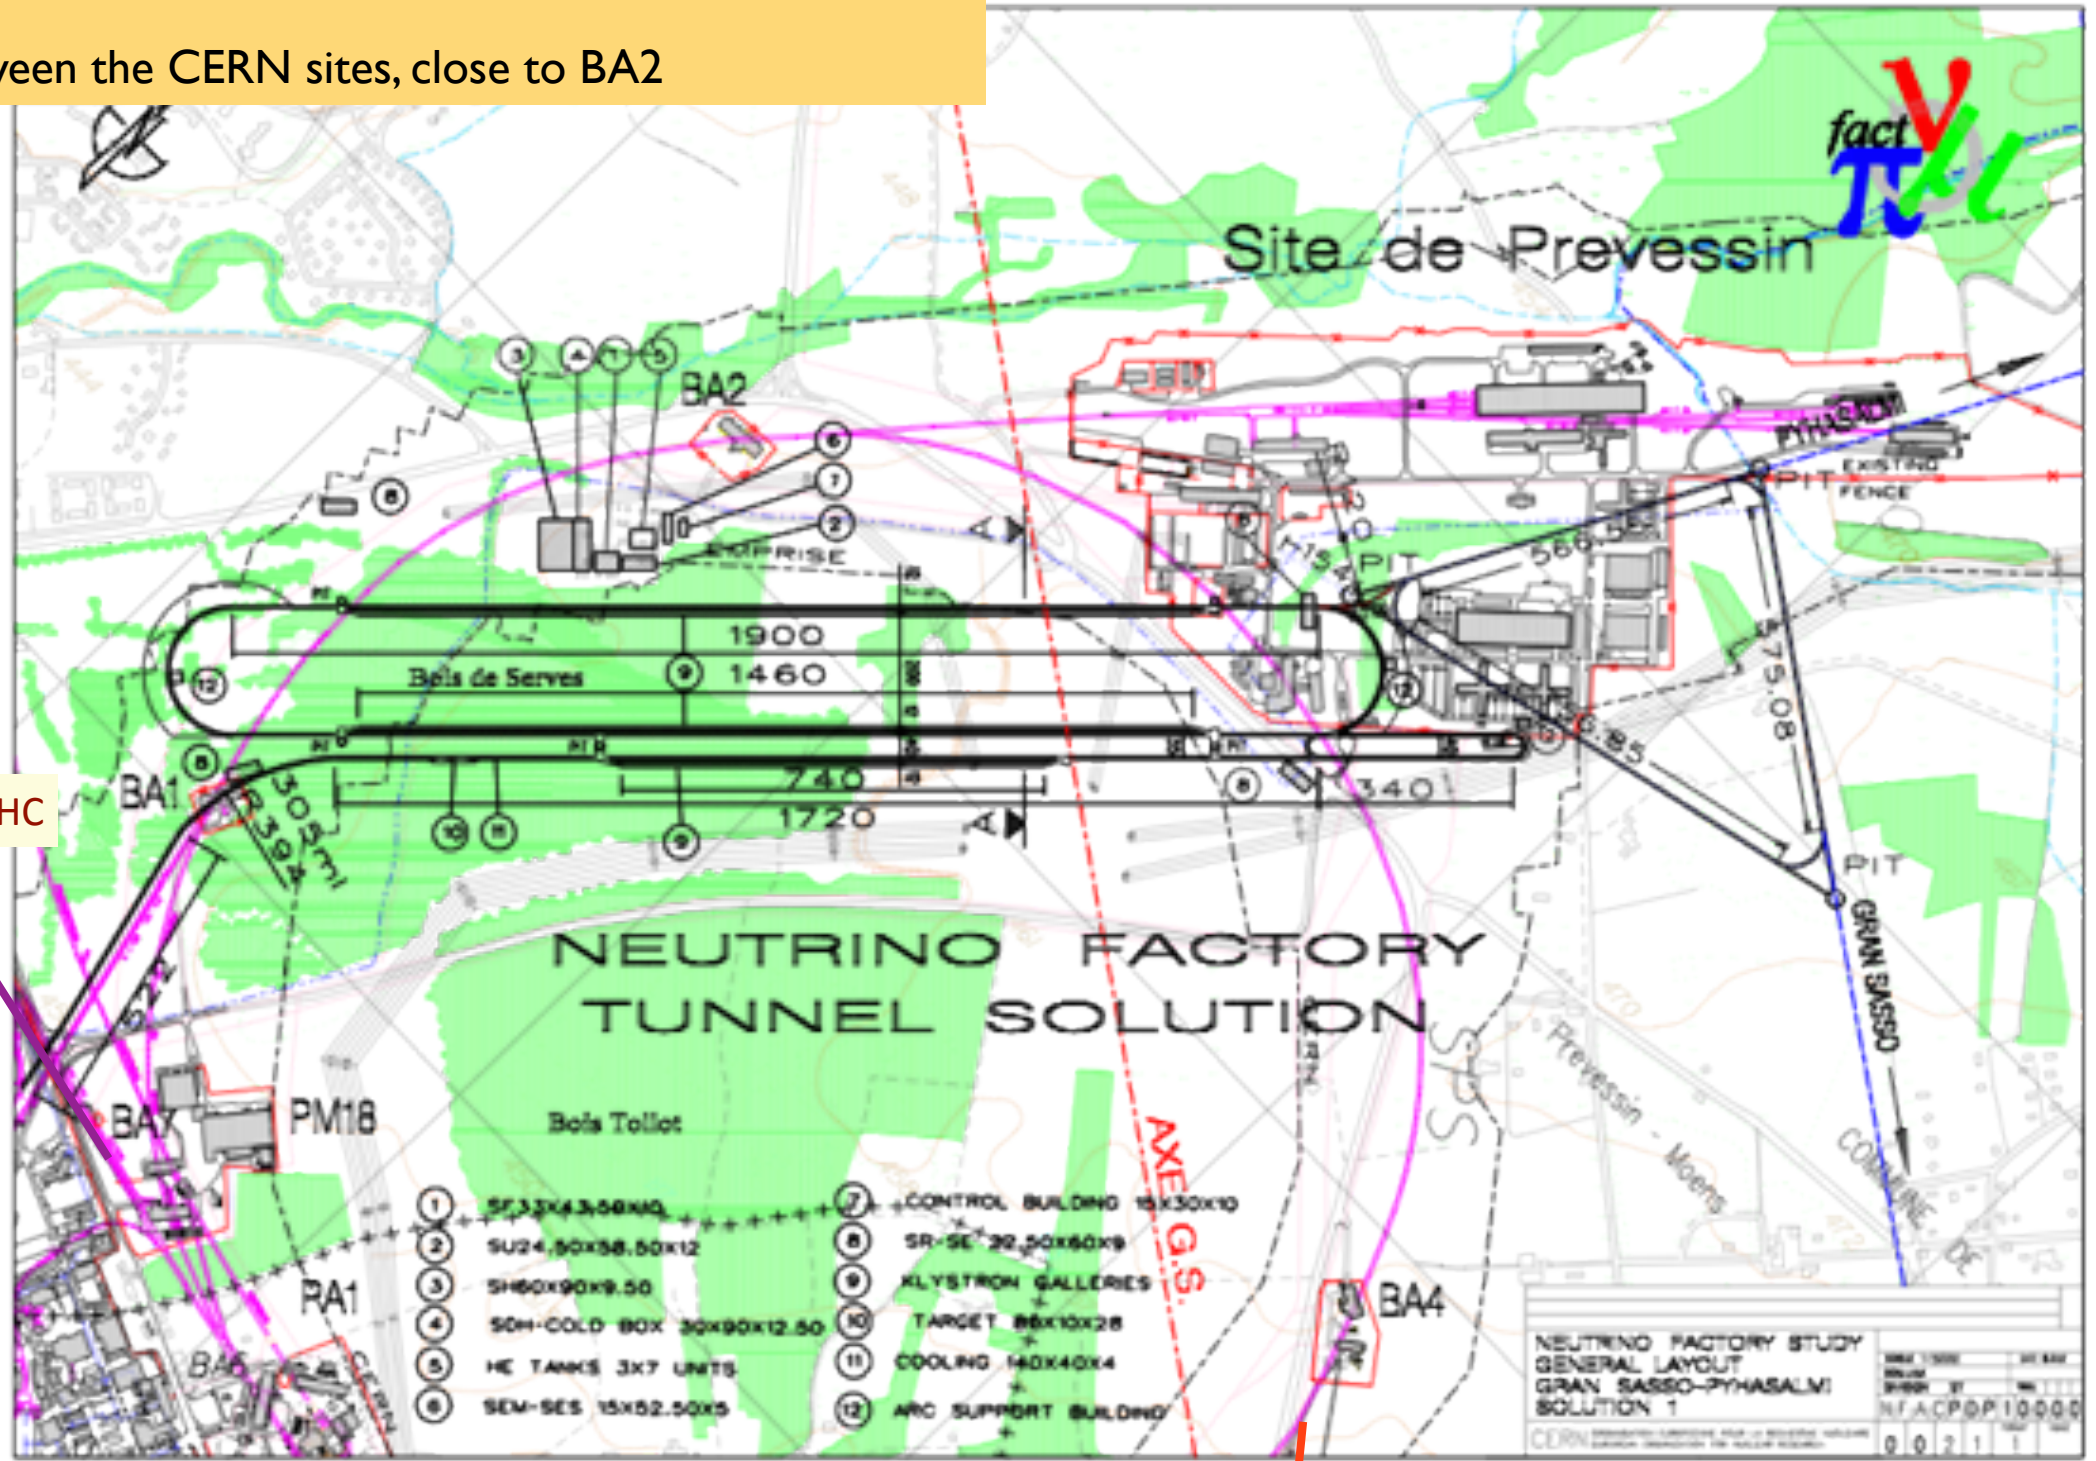

- **CN2PY horn focused neutrino beam towards Pyhäsalmi/FI**
 - ▶ Starting point is SPS and CNGS operation (achieved 420kW)
 - ▶ Protons extraction, transfer & secondary beam lines
 - ▶ Target, horn focusing systems, beam monitors design
 - ▶ Decay tunnel $\approx 300\text{m}$, 10deg dip angle
 - ▶ Low energy optimization; WBB covering 0.5→5 GeV
- **Benefit from improved performance of SPS+injectors; consider further options to upgrade power of SPS (LAGUNA-LBNO WP4)**
- **Upgrade path: HP-PS accelerator (50 GeV) with significant power improvement compared to SPS complex (→ “MW” beam). Exploit synergies with the NF R&D.**

SPS/FT : Operation experience

Realistic SPS proton intensity for LBNO

- We consider the CERN SPS 400 GeV as the only realistic accelerator for the initial LBNO phase. Then, we assume:
 - ★ 85% SPS “sharing” by taking 2 hours/day out for LHC filling
 - ★ 80% efficiency for the accelerators
- Today: SPS intensity is $4e13$ ppp and factor 61% from SPS sharing (situation of today, likely can change within the timescale of LBNO when NA62 or COMPASS physics is completed).
- **In the context of LBNO (>2018)**: the SPS intensity is upgraded (also thanks to LIU project) to $7e13$ ppp at 400 GeV with cycle time = 6 seconds.
 - ★ yearly integrated pot = $(0.8-1.3) \times 1e20$ pot / yr
 - ★ total integrated (12 years) = $(1-1.5) \times 1e21$ pot
 - ★ range corresponds to sharing 60–85%
 - ★ studies ongoing within CERN accelerator team in LAGUNA-LBNO WP4

SPS 400 GeV p.o.t / year

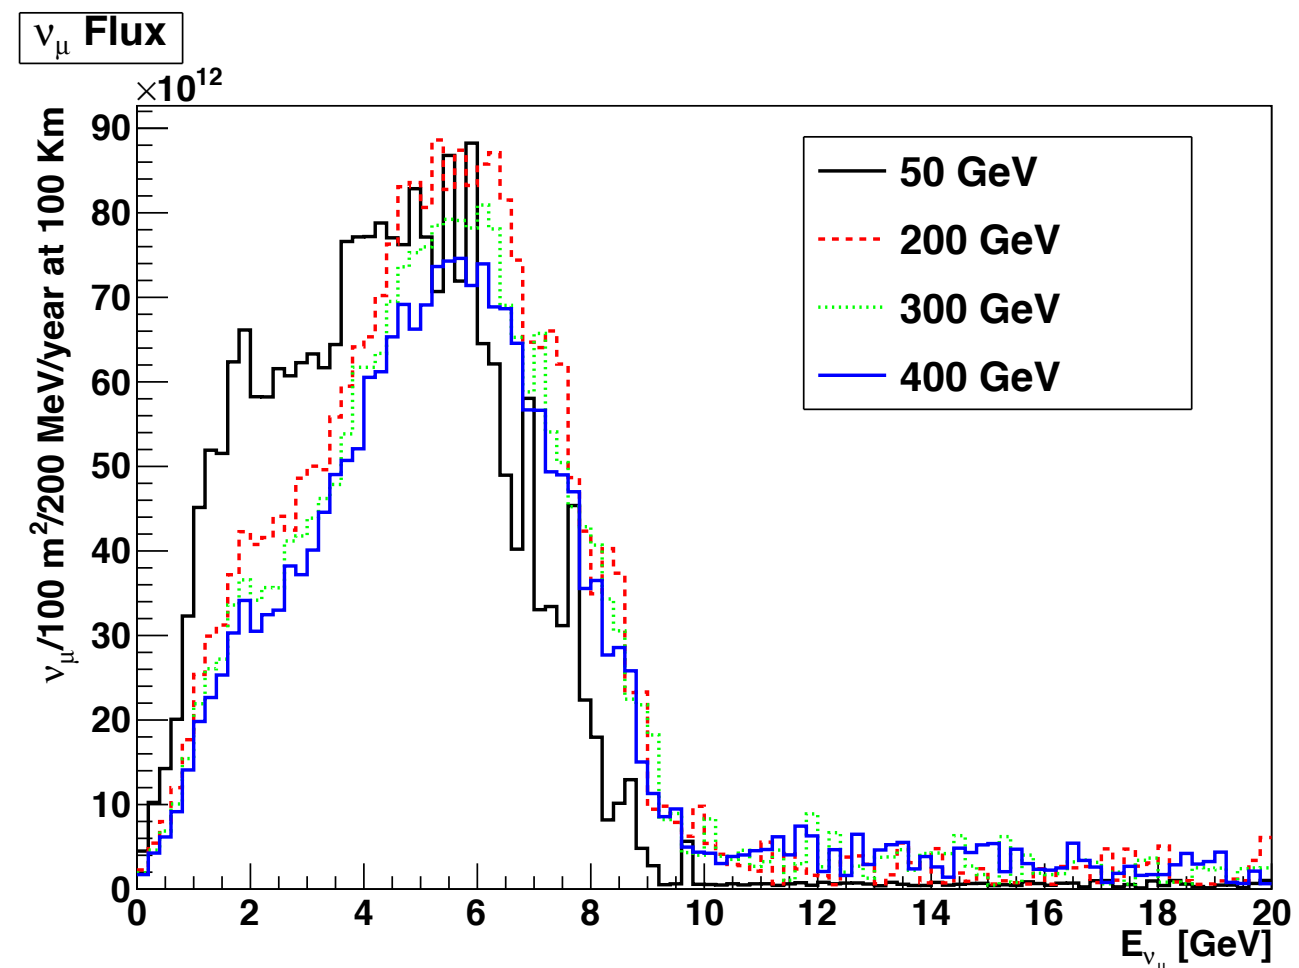

Total integrated p.o.t.

Target, optics optimization

- Preliminary optimization done within LAGUNA DS for various baselines to maximize θ_{13} sensitivity, and assuming 50 GeV protons from HP-PS
- Present activities within LAGUNA-LBNO WP4:
 - Optimization for 50 HP-PS vs 200, 300 and 400 GeV SPS protons
 - Focusing optimization to maximize MH&CPV physics reach.
 - Target optimization.

Expected sensitivity

- We estimate the significance C.L. with a chi2sq method, with which we can
 - 1) exclude the opposite mass hierarchy and
 - 2) exclude $\delta_{CP} = 0$ or π (CPV)
- We minimize chi2sq w.r.t to the known 3-flavor oscillations and the nuisance parameters using Gaussian constraints:

$$\left\{ \begin{array}{l} \Delta m_{32}^{2,0} = (2.40 \pm 0.09) \times 10^{-3} \text{ eV}^2 \\ \sin^2 2\theta_{23}^0 = 0.51 \pm 0.06 \\ \sin^2 2\theta_{13}^0 = 0.10 \pm 0.02 \end{array} \right. \quad \begin{array}{l} \pm 1\sigma \\ \text{present errors} \end{array}$$

- ◆ solar terms fixed
- ◆ include systematic errors (see later)

LAr detector performance

- Based on simulated exclusive final state events (*Qscan* revival part of LAGUNA-LBNO WP5 task).
- Fast simulation through detector geometry.
- Do not simply rely on “Gaussian” parametrizations

Realistic digitization

(based on measured LAr LEM TPC performance):

Neutrino energy reconstruction

- nue CC events generated with GENIE and CN2PY fluxes
- GEANT4
- CCNuE resolution: **8.7% RMS** for vertex in center of detector
- Preliminary result: **$(E_{\text{dep}} - E_{\text{reco}}) / E_{\text{dep}} = 0.7\%$**

top view of detector

deposited energy in fiducial volume

neutrino energy

μ -like sample

e-like sample

Analysis method (=myfitter)

- Based on simulated exclusive final state events. Fast simulation through detector geometry.
- Binned chi2sq method:

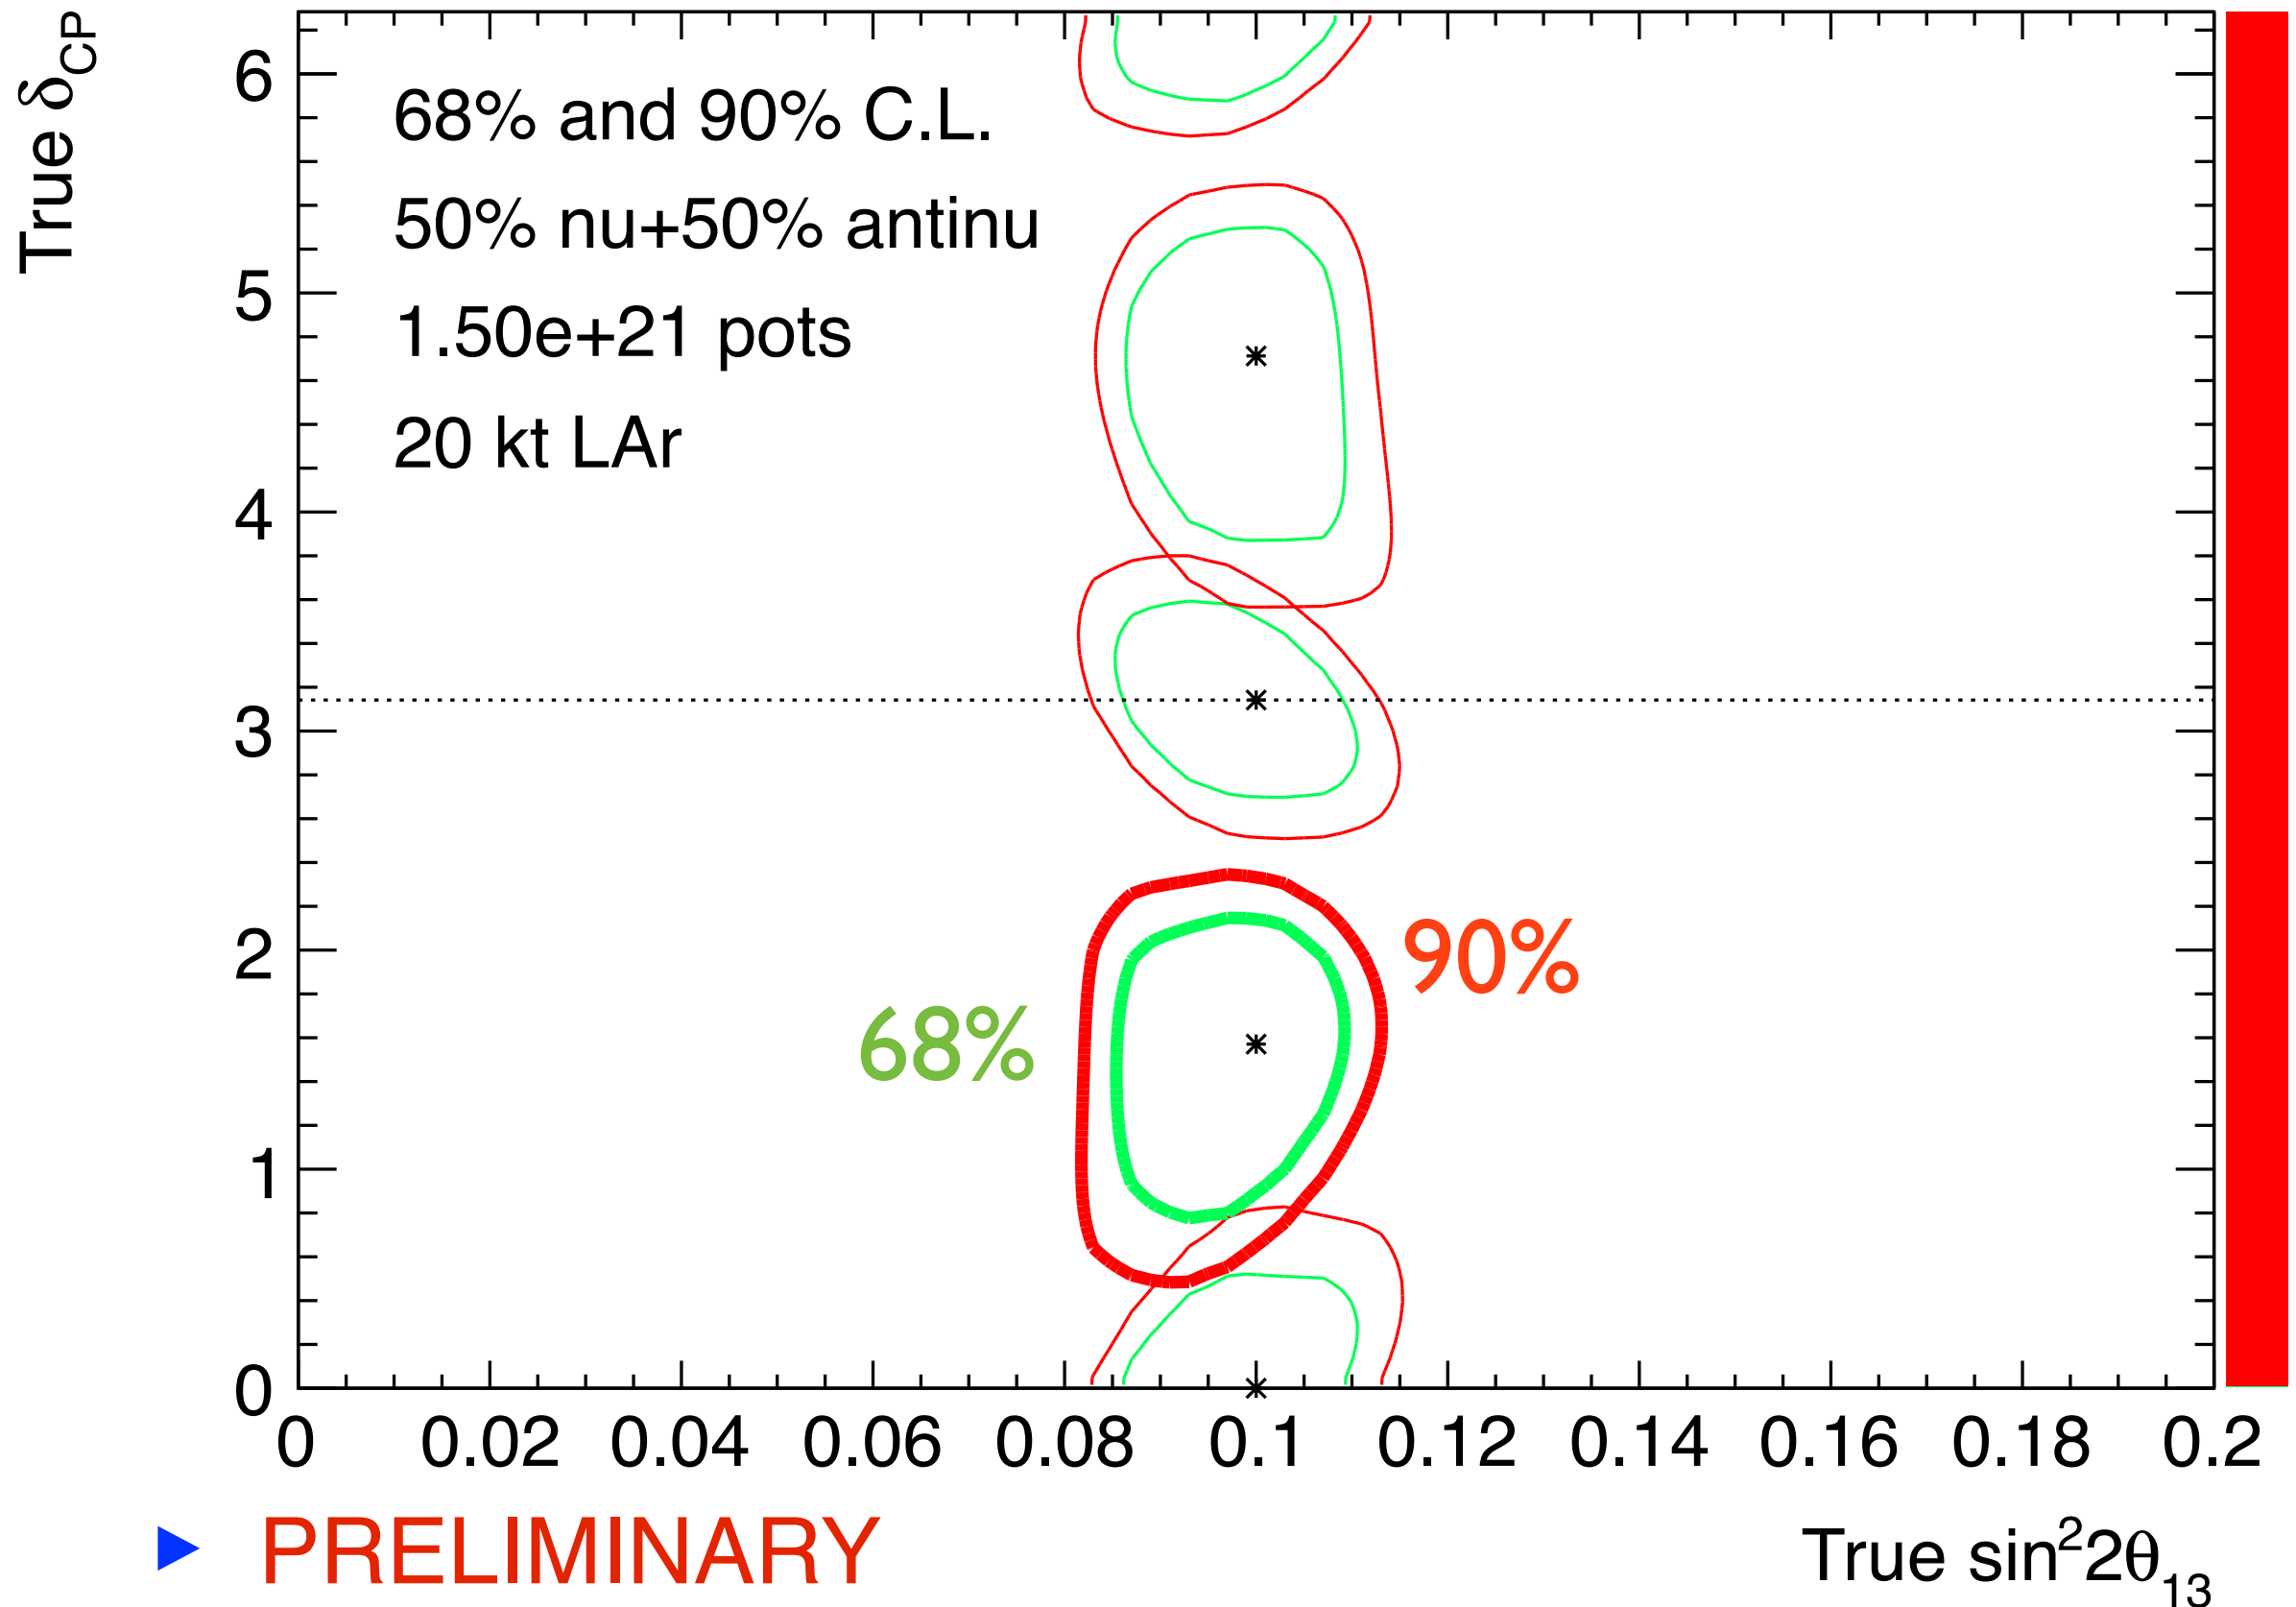

$$\chi^2 = \sum_{+,-} \sum_i \left[N^i - \left\{ 1 \pm \frac{1}{2} f_{\nu/\bar{\nu}} \right\} \cdot \left((1 + f_{\text{sig}}) \cdot n_{\text{sig}}^i + (1 + f_{NC}) \cdot n_{NC}^i + (1 + f_{\nu_e CC}) \cdot n_{\nu_e CC}^i + (1 + f_{\nu_\tau CC}) \cdot n_{\nu_\tau CC}^i \right) \right]^2 / N^i + \frac{f_{\text{sig}}^2}{\sigma_{\text{sig}}^2} + \frac{f_{NC}^2}{\sigma_{NC}^2} + \frac{f_{\nu_e CC}^2}{\sigma_{\nu_e CC}^2} + \frac{f_{\nu_\tau CC}^2}{\sigma_{\nu_\tau CC}^2} + \frac{f_{+/-}^2}{\sigma_{+/-}^2},$$

- ▶ +, - = beam (horn) polarity → at present assume 50%-50% sharing between + and - runs
- ▶ N_i = simulated number of expected events in energy bin i
- ▶ n_{xi} = number of expected events from source “x” in energy bin i
- ▶ f_x = systematic error for “x” → at present assume 5% systematic errors for each source

Phase 1 LBL physics start:	2023 ?
Phase 2 incremental step implementation:	>2025 ?

Conclusions

- **LBNO, to be located underground at Pyhäsalmi 2300km away from CERN, has truly unique scientific opportunities:**
 - ➔ conclusive mass hierarchy determination, in a cleaner and more significant way than any other methods/proposals
 - ➔ very good chance to find CPV with the spectral information providing unambiguous oscillation parameters sensitivity. With 10 years at 700kW SPS and 20 kton LAr +MIND (=initial phase), the reach is 30%(70%) CPV coverage at 3σ (90%) C.L. This step will inform future investigations (e.g. systematics).
 - ➔ $>x10$ better sensitivity in several nucleon decay channels
 - ➔ detection of several astrophysical sources and fresh new look at atmospheric neutrinos with high granularity and resolution.
- **LBNO defines a clear upgrade path** (long term vision / incremental approach) to fully explore CPV. E.g., a three-fold exposure yields 75% CPV coverage at 3σ C.L. !! Comparable to T2HK and better than “other” proposals with conventional beams. Baseline adopted by NF community and LBNO has magnetized detector in initial phase.
- We are submitting an expression of interest to CERN SPSC. The proposal offers an attractive and effective approach to move neutrino physics forward (in Europe and in a global context) and has a long term vision. **EoI already largely endorsed by the community and open to anyone willing to contribute !**

Flux optimization

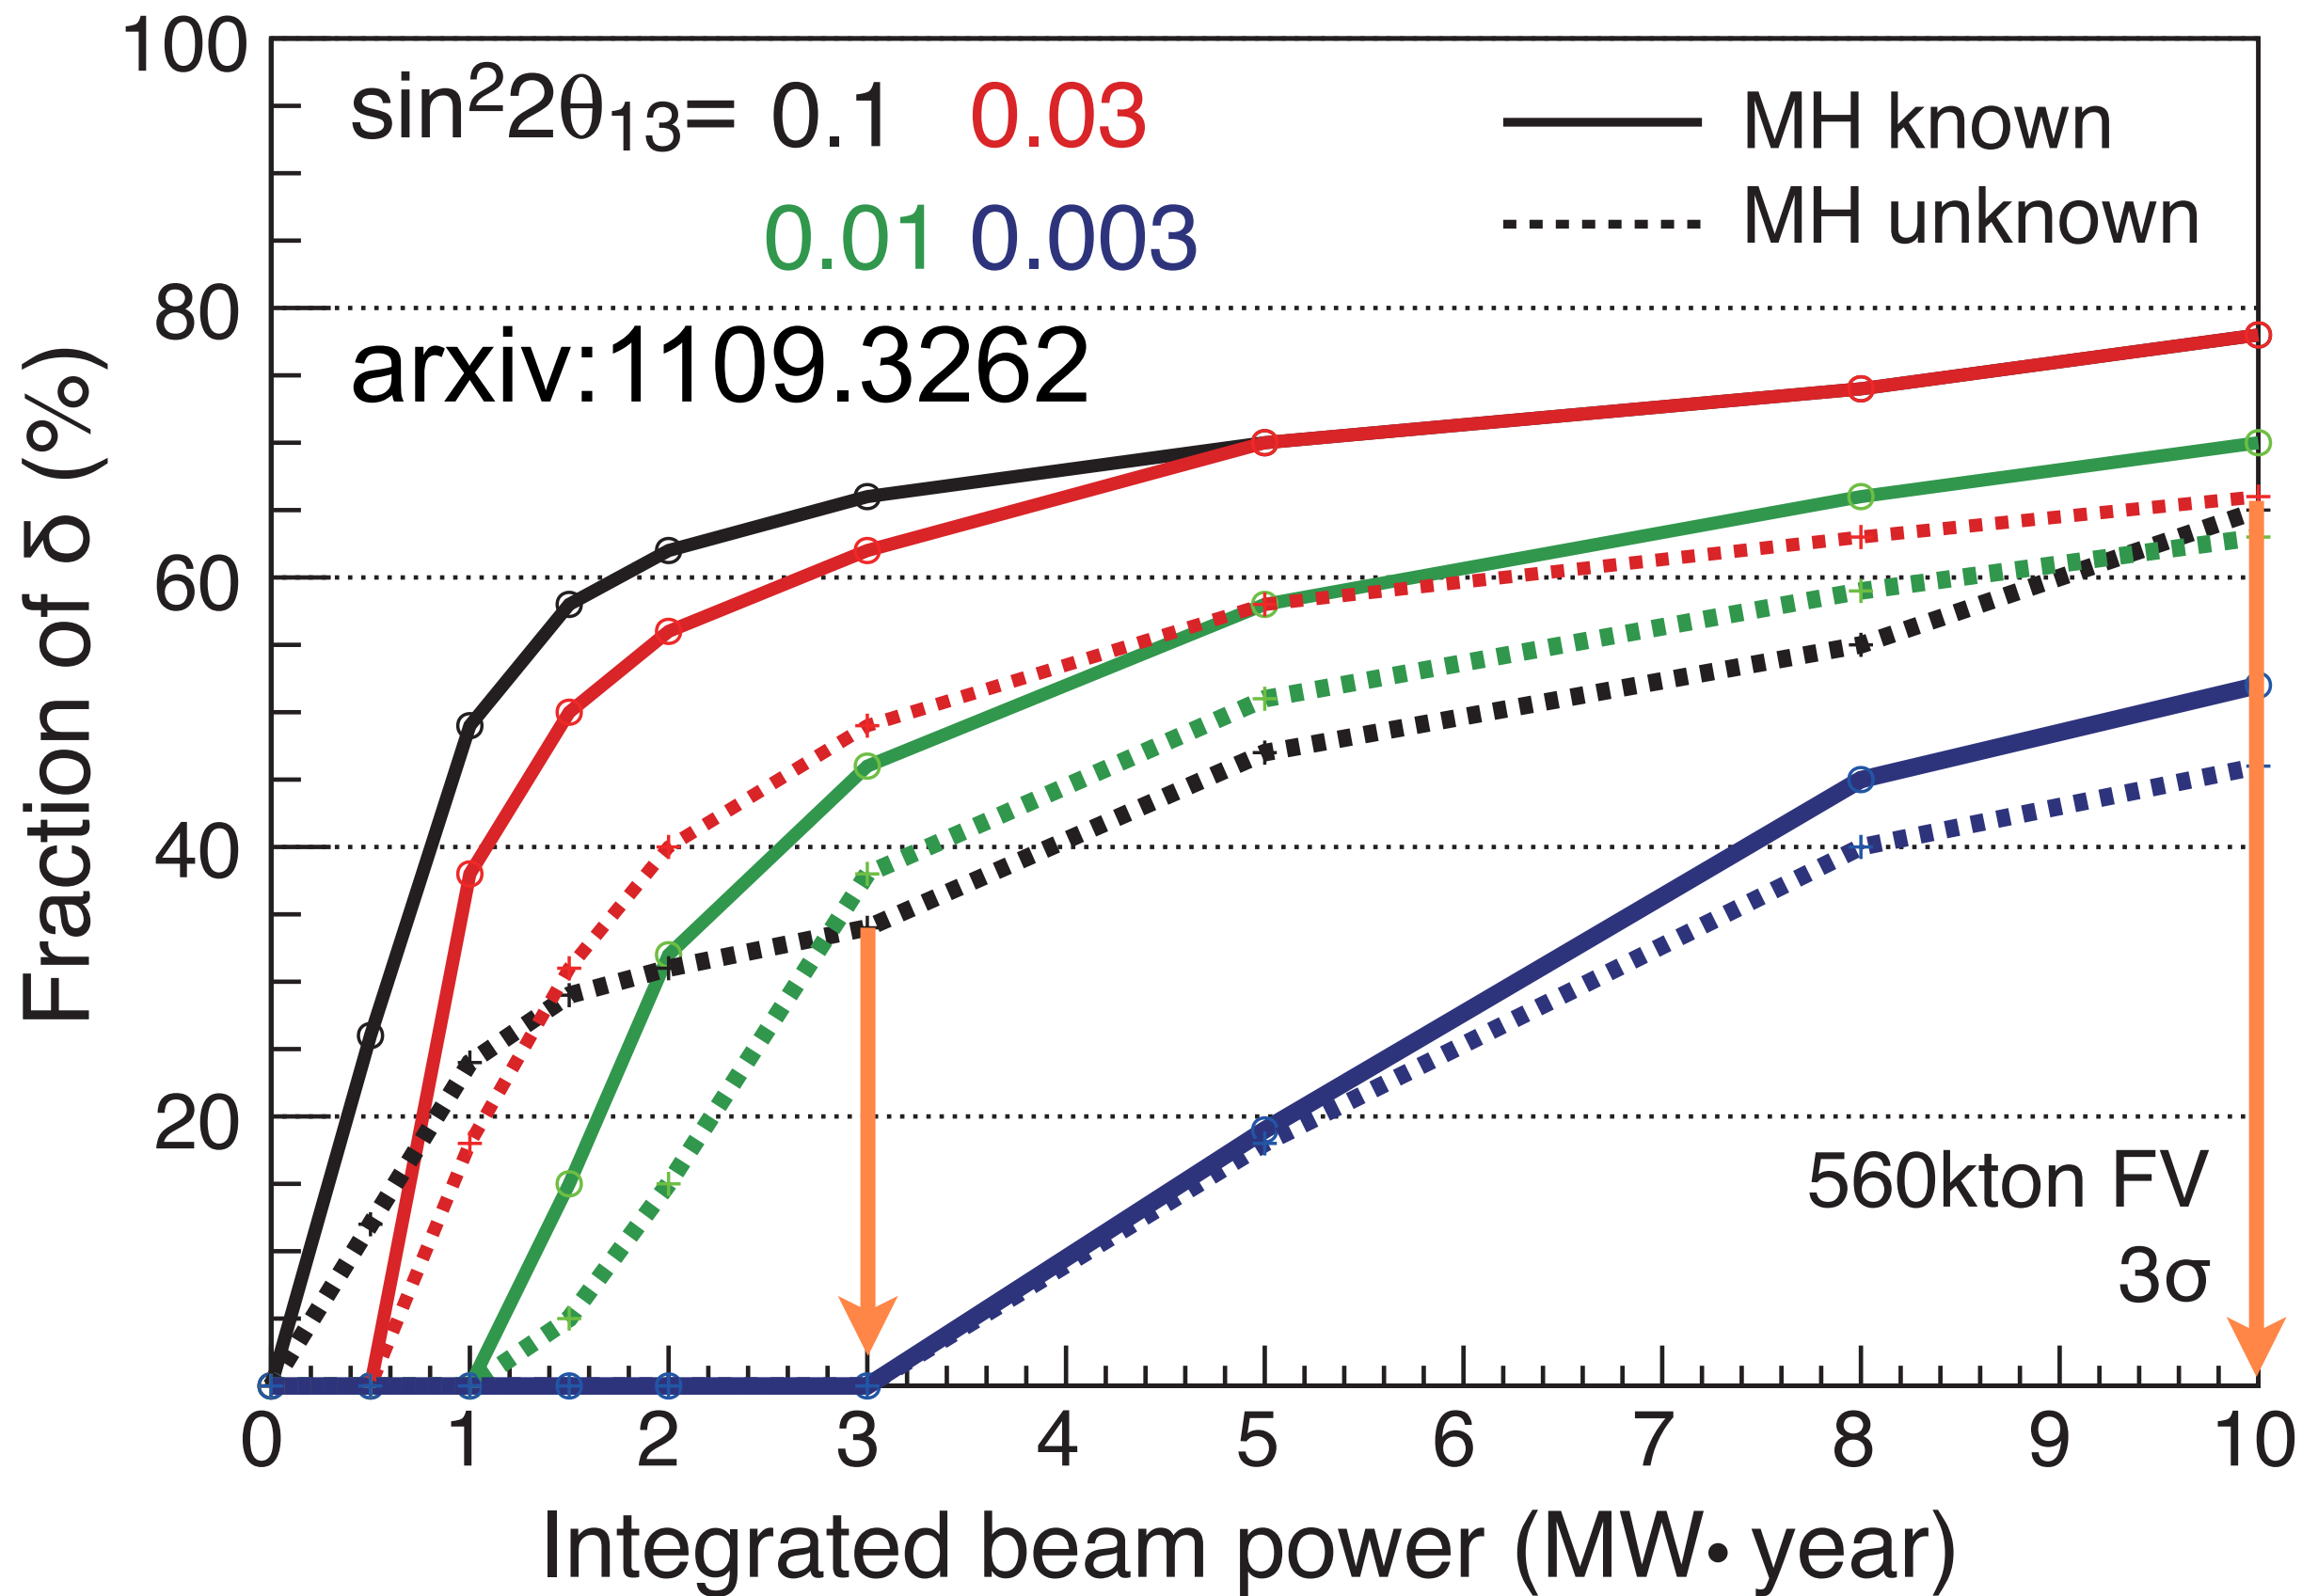

ν_μ Flux at 400 GeV

Why the neutrino mass hierarchy ?

- **CP-violation:** necessary input to solve CPV problem. For example, for the HyperK LOI arxiv:1109.3262 (which considers a 540kton FV and hence has the highest statistical power):
 - 3 MW×years (note: >10 years at present JPARC MR power) MH known: 65% coverage → MH unknown: 35% coverage
 - 10 MW×years needed to reach 65% coverage if MH unknown! rather unlikely within present JPARC projections.
- **$0\nu\beta\beta$ searches:** necessary input to interpret both negative and positive isotope lifetime results, in terms of neutrinos (as opposed to some other source of lepton number violation).
- **BSM/GUT theories:** important ingredient for model building. An inverted hierarchy would have interesting implications.
- **We need a definitive & conclusive determination of the MH !**
