

SHIP *The Particles* **SEARCH FOR HIDDEN PARTICLES**

A New Experiment Proposal

Giovanni De Lellis

Università Federico II and INFN Naples

Italy

Theoretical motivation

- Discovery of the 126 GeV Higgs boson → Triumph of the Standard Model The SM may work successfully up to Planck scale !
- SM is unable to explain:
 - Neutrino masses
 - Excess of matter over antimatter in the Universe
 - The nature of non-baryonic Dark Matter
- All three issues can be solved by adding three new fundamental fermions, right-handed Majorana Heavy Neutral Leptons (HNL): N₁, N₂ and N₃

SM may well be a consistent effective theory all the way up to the Plank scale

- ✓ M_H < 175 GeV → SM is a weakly coupled theory up to the Plank energies !
- ✓ M_H > 111 GeV → EW vacuum is stable or metastable with a lifetime greatly exceeding the age of our Universe (Espinosa et al)

Summary of CMS RPV SUSY Results*

EPSHEP 2013

Bounds on the scale of New Physics

Most stringent limits come from observables in BB mixing

6

Theoretical motivation

- Discovery of the 126 GeV Higgs boson → Triumph of the Standard Model The SM may work successfully up to Planck scale !
- SM is unable to explain:
 - Neutrino masses & oscillations
 - Excess of matter over antimatter in the Universe
 - The nature of non-baryonic Dark Matter
- All three issues can be solved by adding three new fundamental fermions, right-handed Majorana Heavy Neutral Leptons (HNL): N₁, N₂ and N₃

See-saw generation of neutrino masses

Most general renormalisable Lagrangian of all SM particles (+3 singlets wrt the SM gauge group):

$$L_{singlet} = i\bar{N}_I\partial_\mu\gamma^\mu N_I - Y_{I\alpha}\bar{N}_I^c\tilde{H}L_\alpha - M_I\bar{N}_I^cN_I + h.c.$$

Yukawa term: mixing of N_l with active neutrinos to explain oscillations

Majorana term which carries no gauge charge

8

The scale of the active neutrino mass is given by the see-saw formula: $m_{\nu} \sim where m_D \sim Y_{I\alpha}v$ - typical value of the Dirac mass term

 $v\sim 246~{\rm GeV}$

Example:

For $M \sim 1$ GeV and $m_v \sim 0.05$ eV it results in $m_D \sim 10$ keV and Yukawa coupling $\sim 10^{-7}$

The vMSM model

N = Heavy Neutral Lepton - HNL

Role of N_1 with mass in keV region: dark matter Role of N_2 , N_3 with mass in 100 MeV – GeV region: "give" masses to neutrinos and produce baryon asymmetry of the Universe

Masses and couplings of HNLs

• N_1 can be sufficiently stable to be a DM candidate, $M(N_1) \sim 10 \text{ keV}$

•

 M(N₂) ≈ M(N₃) ~ a few GeV → CPV can be increased dramatically to explain Baryon Asymmetry of the Universe (BAU)

Very weak $N_{2,3}$ -to-v mixing (~ U^2) $\rightarrow N_{2,3}$ are much longer-lived than the SM particles

M [GeV]

Dark Matter candidate HNL N₁

Yukawa couplings are small \rightarrow *N* can be very stable.

Main decay mode: $N \rightarrow 3\nu$. Subdominant radiative decay channel: $N \rightarrow \nu\gamma$.

Photon energy:

 $E_{\gamma}=rac{M}{2}$

Radiative decay width:

$$\Gamma_{\rm rad} = \frac{9 \,\alpha_{\rm EM} \,G_F^2}{256 \cdot 4\pi^4} \, \sin^2(2\theta) \, M_N^5$$
Interaction strength 11

Constraints on DM HNL N₁

- ✓ **Stability** → N_1 must have a lifetime larger than that of the Universe
- ✓ Production → N₁ are created in the early Universe in reactions $l\bar{l} \to \nu N_1$ $q\bar{q} \to \nu N_1$ etc. Need to provide correct DM abundance
 ✓ Structure formation → N₁ should be heavy enough! Otherwise its free streaming length would erase structure non-uniformities at small scales (Lyman-α forest spectra of distant quasars and structure of dwarf galaxies)
- ✓ **X-ray spectra** → Radiative decays $N_1 \rightarrow \gamma v$ produce a mono-line in photon galaxies spectrum.

Searches for DM HNL N₁ in space

- Has been previously searched with XMM-Newton, Chandra, Suzaku, INTEGRAL
- Spectral resolution is not enough (required $\Delta E/E \sim 10^{-3}$)
- Proposed/planned X-ray missions with sufficient spectral resolution:

New line in photon galaxy spectrum ???

Two recent publications in arXiv:

- arXiv 1402.2301 Detection of an unidentified emission line in the stacked X-ray spectrum of Galaxy Clusters, $E_{\gamma} \sim 3.56 \text{ keV}$
- arXiv 1402.4119 An unidentified line in X-ray spectra of the Andromeda galaxy and Perseus galaxy cluster, $E_{\gamma} \sim 3.5 \text{ keV}$

Will soon be checked by Astro-H with higher energy resolution

g

Masses and couplings of HNLs

 $M(N_2) \approx M(N_3) \sim a$ few GeV \rightarrow CPV can be increased dramatically to explain Baryon Asymmetry of the Universe (BAU)

Very weak $N_{2,3}$ -to-v mixing (~ U²) $\rightarrow N_{2,3}$ are much longer-lived than the SM particles

• Produced in semi-leptonic decays, $K \to \mu\nu, D \to \mu\pi\nu, B \to D\mu\nu$

Example: $N_{2,3}$ production in charm

- N_{2,3} D π v*H N_{23}

Ds

• $\propto \sigma_D \times U^2$

•
$$U_2^2 = U_{2,\nu_e}^2 + U_{2,\nu_\mu}^2 + U_{2,\nu_\tau}^2$$

and subsequent decays

- Typical lifetimes > 10 μ s for $M(N_{2.3}) \sim 1$ GeV Decay distance O(km)
- *Typical BRs (depending on the flavour mixing):*

 $Br(N \rightarrow \mu/e \pi) \sim 0.1 - 50\%$ $Br(N \rightarrow \mu^{-}/e^{-} \rho^{+}) \sim 0.5 - 20\%$ $Br(N \rightarrow v\mu e) \sim 1 - 10\%$

Baryon asymmetry

Sakharov conditions:

• C and CP are not conserved in vMSM

6 CPV phases in the lepton sector and 1 CKM phase in the quark sector (to be compared with only one CKM phase in the SM)

- Deviations from thermal equilibrium
- ✓ HNL are created in the early Universe
- ✓ CPV in the interference of HNL production and decay
- ✓ Lepton number goes from HNL to active neutrinos
- Then lepton number transfers to baryons in the equilibrium sphaleron processes
 - **PS** Explanation of DM with N_1 reduces a number of free parameters \rightarrow Degeneracy of $N_{2,3}$ masses is required to ensure sufficient CPV

Masses and couplings of HNLs

Very weak $N_{2,3}$ -to-v mixing (~ U^2) $\rightarrow N_{2,3}$ are much longer-lived than the SM particles

• Typical BRs (depending on the flavour mixing):

Br(N → μ/e π) ~ 0.1 - 50% Br(N → μ⁻/e⁻ ρ⁺) ~ 0.5 - 20% Br(N → νμe) ~ 1 - 10%

Experimental and cosmological constraints

- The sensitivity of previous experiments did not probe the interesting region for HNL masses above the kaon mass
- Strong motivation to explore cosmologically allowed parameter space

Proposal for a new experiment at the SPS, SHIP to search for new long-lived particles produced in charm decays (see http://ship.web.cern.ch/ship) Experimentally this domain has not been well explored!

Sensitivity for $N_{2,3} \propto U^4$

- PS-191: Used K decays \rightarrow limited to 500 MeV (PLB 203 (1988) 332)
- Goal: Extend mass range to ~ 2 GeV by using charmed hadron decays
- B-decays: 20÷100 smaller σ , and B \rightarrow Dµv, i.e. limited to 3 GeV still

Where to produce charmed hadrons?

LHC ($\sqrt{s} = 14$ TeV): with 1 ab^{-1} (~ 3-4 years): ~ 2 × 10¹⁶ in 4 π SPS (400 GeV *p*-on-target (pot) $\sqrt{s} = 27$ GeV): with 2 × 10²⁰ pot (~ 3-4 years): ~ 2 × 10¹⁷

Moreover, the acceptance of a beam dump facility can be much larger for long lived particles ¹⁹

Experimental requirements

• Search for HNL in Heavy Flavour decays

Beam dump experiment at the SPS with a total of 2×10²⁰ protons on target (pot) to produce a large number of charmed hadrons CNGS: 1.8 x 10²⁰ pot, 2011 run: 4.8 x 10¹⁹ pot

• HNLs produced in charm decays have significant P_{T}

Detector must be placed close to the target to maximize geometrical acceptance

Effective (and "short") muon shield is essential to reduce
 muon-induced backgrounds (mainly from short-lived resonances accompanying charm production) 20

Shield (W, Fe)

Magnet

Generic setup, not to scale!

21

Detector concept (based on existing technologies)

• Reconstruction of the HNL decays in the final states: $\mu^-\pi^+$, $\mu^-\rho^+$ & $e^-\pi^+$

Requires long decay volume, magnetic spectrometer, muon detector and electromagnetic calorimeter, preferably in surface building

Detector concept (cont.)

Geometrical acceptance

- Saturates for a given HNL lifetime as a • function of detector length
- The use of two magnetic spectrometers • increases the acceptance by 70%

Detector has two almost identical elements

23

Tracking chambers

Same as NA62 $(K^+ \rightarrow \pi^+ \nu \bar{\nu})$ 2m diameter vessel at 0.01 µbar 10 mm diameter straws made of PET \rightarrow working well in vacuum $X/X_0 = 0.5\%$ for 4 view stations 120 µm resolution/straw

Magnet and e.m. calo

- \bullet With X/X0=0.5~% chambers: modest 0.5 Tm
- Need $\sim 20~m^2$ aperture.

LHCb magnet: 4 Tm, 16 m^2 aperture Preliminary calculations (W.Flegel):

- $\bullet~{\rm Needs}~30~\%$ less iron/yoke than LHCb.
- Consumes 3 times less power.

- 6.3×7.8 m²
- $\frac{\sigma(E)}{E} < 10\%/\sqrt{E} \oplus 1.5\%$

Mass resolution

Expected resolution for 1 GeV N $\rightarrow \mu \pi$ $\langle p_N \rangle = 25 \text{ GeV}$

- σ_{mass} ~ 40 MeV for P < 20 GeV
- K⁰_L background suppression
- Use pointing of candidates to target area
- Detect CC via extra μ in coincidence with $\mu\pi$, upstream tagger
- *Instrument* μ*-filter to tag CC/NC shower*

Expected event yield

Assuming $U_{\mu}^{2} = 10^{-7}$ (corresponding to the strongest experimental limit currently for $M_{N} \sim 1$ GeV) and $\tau_{N} = 1.8 \times 10^{-5}$ s

~12k fully reconstructed N $\rightarrow \mu^{-}\pi^{+}$ events are expected for M_{N} = 1 GeV

120 events for cosmologically favoured region: $U_{\mu}^{2} = 10^{-8} \& \tau_{N} = 1.8 \times 10^{-4} s_{27}$

Sensitivity to HNL: U_e

Physics case for a beam dump facility

hidden sector:

HNL: baryon asymmetry of the Universe, dark matter, neutrino masses sgoldstino, light neutralino: SUSY paraphoton: mirror matter, dark matter

Physics case for general beam dump facility

\checkmark Study of v_{τ} interactions (guarantied SM physics)

Ideally suited since v_{τ} is produced in $D_s \rightarrow \tau v_{\tau}$ with similar to HNL kinematics. DONUT 9 events, OPERA 4 events (from oscillations)

- ✓ Search for any weakly interacting yet unstable particles produced in very rare charm (or hyperon) decays such as low mass SUSY or paraphotons or ...
- ✓ Review of the SHIP sensitivities for v_{τ} physics and wide class of models with hidden portals is ongoing

Expect significant improvement of currently available measurements and constrains everywhere!

A powerful source of neutrinos originated by charm decays, $D_s \rightarrow \tau v_{\tau}$ Present configuration, flux rates: $v_e \sim 7.1\%$, $v_{\mu} \sim 92.5\%$, $v_{\tau} \sim 0.4\%$ Anti- $v_{\mu} / v_{\mu} \sim 62\%$, Anti- $v_e / v_e \sim 1$, Anti- $v_{\tau} / v_{\tau} = 1$

- Expect ~ 3400 v_{τ} interactions in 6 tons emulsion target (~5% of the OPERA emulsion films)
- Tau neutrino and anti-neutrino (never seen) physics
- Charm physics with neutrinos and anti-neutrinos
- v_{τ} : a probe of non-standard interactions PRD 87 (2013) 013002

A neutrino detector upstream

Detector choice

- Neutrino target: high density material (lead) alternated with emulsions (Emulsion Cloud Chamber).
- Vertex detector: emulsions as micrometric tracking device to see both the neutrino interaction and τ decay vertices.
- Nuclear fragments \rightarrow reduce background from hadronic int. (track angles up to $\vartheta \sim \pi/2$)
- Momentum measurement of hadrons (several GeV) by Multiple Coulomb Scattering with ~ 20% accuracy in the several GeV range
- High resolution tracker to provide the time stamp and reconstruct the μ track in the target (~ 100 μ m)
- Muon spectrometer to measure charge and momentum. Focus on the acceptance to low energy and large angle μ (as μ from ν_{μ} int., charmed interactions particularly important)

Detector design, beam view Magnetic muon shield \rightarrow elongate the target along the magnetic field \rightarrow rectangular shape

Detector design: first option

Wall thickness ~ 13 cm: 8 cm brick + 5 cm tracker plane

Detector design: second option with a magnetized target

Compact emulsion spectrometer CES

- 3 emulsion films interleaved with 1.5 cm air gap in a magnetic field (~ 1T), 3cm thick device, H. Shibuya et al NIM A592 (2008) 56
- Emulsion films alternated by low density material (Rohacell, 30÷100 kg/m³)
- With a good alignment, by means of high energy μ, the charge of 10 GeV muons detectable (±4 μm displacement).

Charge Measurement with CES Geant4 simulation

^{15/07/14} Neutrino Event Generator tuned with NOMAD data

Real-time electronic detectors

- Time stamp of the event, association of tracks in emulsions with tracks in the target tracker
- In an environment with high interaction rate, a high resolution $(\sim 100 \ \mu m)$ is needed. Identified options: 250 μm scintillating fibre tracker; GEM; MicroMegas.
- The muon spectrometer has to identify μ with high efficiency
- Charm background from μ mis-identification.
- Charge measurement is less important than μ identification in this respect
- Charge measurement important for v_{τ} and anti- v_{τ} separation

Muon detector requirements

- Detector performances driven by the background rejection → minimise muon misidentification
- Soft and large angle muons \rightarrow difficult to be identified
- Large acceptance and fine graining to identify P < 2 GeV
- $4 \ge 5.5 \text{ m}^2$ to detect angles up to $\tan(\vartheta) \le 1$
- High sampling to use momentum/range correlation

The magnetic spectrometer (OPERA one is an option)

Charm bkg rejection in v_{μ} CC events Muon identification (with TT) > 95% $\Delta p/p < 20\%$ for p<30 GeV Charge misidentification < 0.3%

OPERA RPC's

1 RPC row: 3 chambers in a series (~9 m²) Basic unit of gas flow and HV $I > 4 \mu A / 9 m^2$

HV cable failure (thin cables)

- 1008 RPC chambers for a surface ~3200 m²
- 22+2 layers (RPC+XPC) for each SM
- 1 layer = 21 RPCs of $2.9*1.1 \text{ m}^2$
- Read-out strips of ~8 m, 2.6 cm pitch for bending and 3.5 cm pitch for orthogonal view
- Total digital electronics channels ~ 28000

Typical current/rates: 500 nA/row / 1 kHz/layer In SM2 2/168 (1.2%) rows I > 4 μ A/9m² Rates of high current layers: 10 kHz 2 RPC rows (1.2%) off because of HV failures (cable insulation)

Muon identification

- Same configuration as OPERA, 5 cm iron slabs interleaved with active (RPC) trackers, 4 x 5.5 m²
- Exploit the momentum-range correlation
- $\varepsilon_{\mu} \sim 92\%$ for charm v_{μ} events (~3% out of acceptance)
- $\varepsilon_{\mu} \sim 94\%$ for $\tau \rightarrow \mu$ events

Momentum resolution by range in the second arm ~7%

Signal to noise

$\frac{\nu_{\tau}}{\bar{\nu}_{\mu_{CC}}^{charm}} = \frac{\int \phi_{\nu_{\tau}} \cdot \sigma_{\nu_{\tau_{CC}}} dE}{\int \phi_{\bar{\nu}_{\mu}} \cdot \sigma_{\bar{\nu}_{\mu_{CC}}^{charm}} \cdot \eta_{mis} dE} \sim \frac{6 \times 10^{-3} \times 300}{8 \times 10^{-2}} \sim 20$

In anti- v_{τ} interactions

$$\frac{\bar{\nu}_{\tau}}{\nu_{\mu_{CC}}^{charm}} = \frac{\int \phi_{\bar{\nu}_{\tau}} \cdot \sigma_{\bar{\nu}_{\tau_{CC}}} dE}{\int \phi_{\nu_{\mu}} \cdot \sigma_{\nu_{\mu_{CC}}^{charm}} \cdot \eta_{mis} dE} \sim \frac{3.7 \times 10^{-3} \times 90}{8 \times 10^{-2}} \sim 4$$

Effect of the angular acceptance not accounted Kinematical selection not included

In OPERA Signal/noise ~ 10 on average Signal/noise ~ 30 in the leptonic channels ($\varepsilon_{\mu} \sim 98\%$)

New physics in v_{τ} scattering A. Datta et al., PRD 87 (2013) 013002

Several new physics models may contribute to v_{τ} scattering

15/07/14

The lines correspond to different sets of the couplings $(g_L^{\tau\nu_{\tau}}, g_L^{ud}, g_R^{ud})$.

The lines correspond to different values of $\tan\beta$ (ratio of VEV's)

Expected v-induced charm events

Charm background in the v_{τ} search from electron mis-identification ($v_e \sim 10\%$)

Associated charm production

Only gluon bremsstrahlung in CC interactions Both processes in NC

Fig. 1. Feynman diagrams for bosongluon fusion (left) and gluon bremsstrahlung processes (right)

3 events in NC and 1 in CC processes, another CC event observed with a different search

$$\frac{\sigma(c\bar{c}\nu)}{\sigma_{\rm NC}^{\rm DIS}} = (3.62^{+2.95}_{-2.42}({\rm stat}) \pm 0.54({\rm syst})) \times 10^{-3}. \qquad \qquad \frac{\sigma(c\bar{c}\mu^{-})}{\sigma_{\rm CC}} < 9.69 \times 10^{-4},$$

~ 30 events expected

Double charm in NC interactions sensitive to the existence of Z' bosonsCharm production induced by v_{τ} interactions is competing15/07/14Same topology, kinematics to be exploited

Search for multi-quark states in v interactions: charmed pentaquarks

Weakly decaying charmed hadron (below 2.8 GeV)

Unlike other processes like e+ e- scattering, the θ_c^0 production in anti-neutrino interactions is favoured by the presence of three valence quarks

G. De Lellis et al. / Nuclear Physics B 763 (2007) 268-282

Fig. 1. Θ_c^0 production in $\bar{\nu}_{\mu}$ interactions.

Fig. 2. Decay topology of Θ_c^0 events produced in $\bar{\nu}_{\mu}$ interactions with two and four prongs.

$$\sigma_{\Theta_c^0} / \sigma_{\bar{\nu}} < 0.039$$
 at 90% C.L.

lifetime equal to $0.5\tau_{D^0}$

Not a tight bound, larger than D⁰ prod, Limited by the anti-nu statistics

New physics portals

- Fermion portal
 - HNL in general
 - SUSY: Low mass neutralinos
- Scalar portal
 - Light inflaton
- Vector portal
 - Paraphoton
- Axion portal
 SUSY: Light sgoldinos

In general: sensitive to very weakly interacting and long lived particles

Light neutralinos

- ✓ Can be produced in charm decays, e.g. $D^0 \rightarrow v \chi_0$, $D^+ \rightarrow \mu^+ \chi_0$
- ✓ Decay final states:

Hidden photons

Assuming no lighter hidden particles, γ' decay into SM particles through a virtual photon:

- decay length $c\tau \sim \varepsilon^{-2} m_{\gamma'}^{-1}$
- cosmological constraints (nucleo-synthesis): $\tau < 0.1 ~ {\rm s} \Rightarrow \varepsilon^2 m_{\gamma'} > 10^{-21} ~ {\rm GeV}$

 γ' production

- proton bremsstrahlung:
 - initial-state radiation from the incoming proton, followed by a hard proton-nucleus interaction
- secondary particles decay:

Mass interval (GeV)	Process	$n_{\gamma'}/p.o.t$
$m_{\gamma'} < 0.135$	$\pi^0 \to \gamma \gamma'$	$\varepsilon^2 \times 5.41$
$0.135 < m_{\gamma'} < 0.548$	$\eta ightarrow \gamma \gamma'$	$\varepsilon^2 \times 0.23$
$0.548 < m_{\gamma'} < 0.648$	$\omega ightarrow \pi^0 \gamma'$	$\varepsilon^2 imes 0.07$
$0.648 < m_{\gamma'} < 0.958$	$\eta' \to \gamma \gamma'$	$\varepsilon^2 \times 10^{-3}$

Only e^+e^- and $\mu^+\mu^-$ decays considered here R used to compute the dark photon lifetime ⁵⁵

Sensitivity to Dark photons Preliminary result: 90% C.L. limit

Sensitivity to Dark photons

90% C.L. Preliminary

Status of the SPSC review

- Oct 2013: submitted our EOI: CERN-SPSC-2013-024 ; arXiv:1310.1762 ; SPSC-EOI-010. 2013
- SPSC assigned 4 referees, who came with a list of questions.
- 3/1/2014: answers to questions: snoopy.web.cern.ch/snoopy/EOI/SPSC-EOI-010_ResponseToReferees.pdf
- 15/1/2014: SPSC discussed our proposal.

17/1/2014: The official feedback from the Committee is as follows :

"The Committee received with interest the response of the proponents to the questions raised in its review of EOI010.

The SPSC **recognises** the interesting physics potential of searching for heavy neutral leptons and investigating the properties of neutrinos.

Considering the large cost and complexity of the required beam infrastructure as well as the significant associated beam intensity, such a project should be designed as a general purpose beam dump facility with the broadest possible physics programme, including maximum reach in the investigation of the hidden sector.

To further review the project the Committee **would need** an extended proposal with further developed physics goals, a more detailed technical design and a stronger collaboration."

Cheers,

Gavin, Lau, Matthew and Thierry

(for the SPS Committee).

Planning schedule of the SHIP facility

A few milestones:

- ✓ Form SHIP collaboration
- ✓ Technical proposal
- ✓ Technical Design Report
- \checkmark Construction and installation
- ✓ Commissioning
- ✓ Data taking and analysis of 2×10^{20} pot → 2023 2027

- → June-September 2014
- → 2015
- → 2018
- → 2018 2022
- → 2022

Conclusion and Next steps

- The proposed experiment will search for NP in the largely unexplored domain of new, very weakly interacting particles with masses below the Fermi scale
- Detector is based on existing technologies
 Ongoing discussions of the beam lines with experts
- The impact of HNL discovery on particle physics is difficult to be overestimated!
- The proposed experiment complements the searches for NP at the LHC and in neutrino physics
- Tau neutrino physics and charm physics with neutrinos

A Collaboration is currently being setup. The first collaboration meeting was held in June. Let us know if you are interested to join!
