## Nuclear Data for Science and Technology

### The quest for accurate nuclear data

- Cross section: capture, fission, inelastic
- Multiplicity and energy spectrum of neutron
- Delayed neutron
- Fission fragments: mass distribution
- $\beta$  decay

So far, only data relevant to U/Pu thermal reactor are present. New needs:

1. High neutron energies (fast reactors)
2. Radioactive isotopes (e.g. involved in the fuel cycle)
3. New fuel cycle (U/Th)

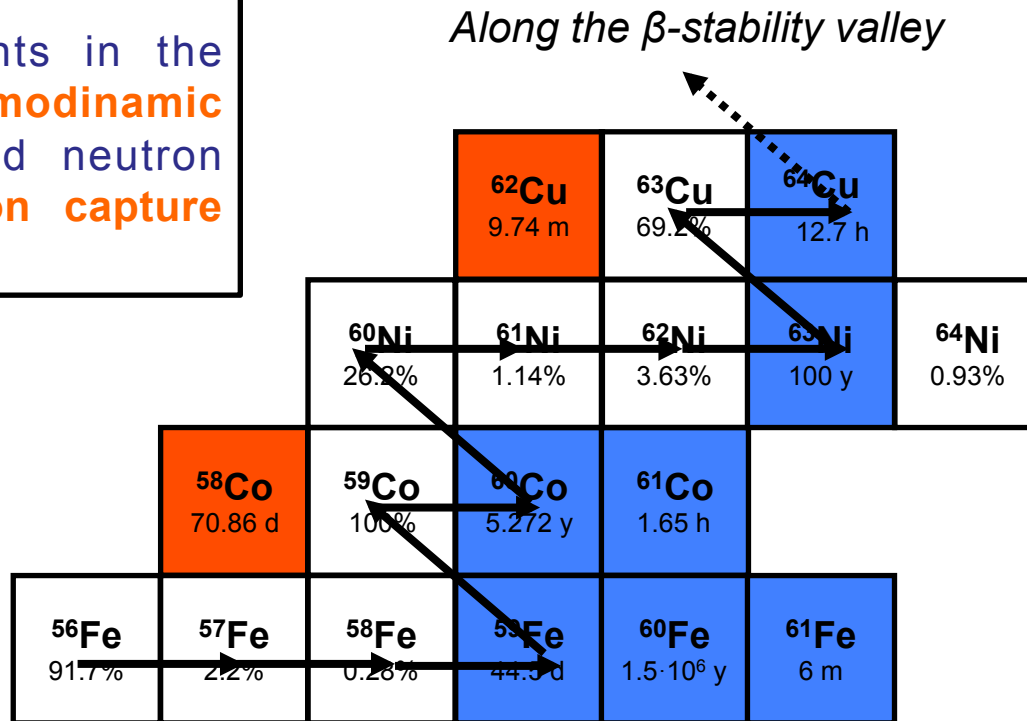

## Nuclear Data for Science and Technology

s-process nucleosynthesis proceeds through **neutron captures** and successive  **$\beta$ -decay**.

The abundance of elements in the Universe depends on **thermodynamic conditions** (temperature and neutron density) and on the **neutron capture cross-sections**.

$\sigma(n, \gamma)$  is a key quantity

s process

## Nuclear Data for Science and Technology

# The n\_TOF project

## Nuclear Data for Science and Technology

The European Commission encourages and finances research in nuclear physics applied to the construction of new reactors (EURATOM).

### FP VII EURATOM

**Topic: Fission-2009-2.3.2: Improved nuclear data for advanced reactor systems.**

The combination of advanced simulation systems and more precise nuclear data will allow optimising the use of and need for experimental and demonstration facilities in the design and deployment of new reactors. A concerted effort including new nuclear data measurements, dedicated benchmarks (i.e. integral experiments) and improved evaluation and modelling is needed in order to achieve the required accuracies. **The project shall aim to obtain high precision nuclear data for the major actinides present in advanced reactor fuels**, to reduce uncertainties in new isotopes in closed cycles with waste minimisation and to better assess the uncertainties and correlations in their evaluation.

### THE FIRST NEUTRON BEAM HITS EAR2

On 25 July 2014, about a year after construction work began, the Experimental Area 2 (EAR2) of CERN's neutron facility n\_TOF recorded its first beam. Unique in many aspects, EAR2 will start its rich programme of experimental physics this autumn.

The last part of the EAR2 beamline: the neutrons come from the underground target and reach the top of the beamline, where they hit the samples.

**A word from the DG**

**GETTING TO KNOW INTERNATIONAL GENEVA**

Over recent years, CERN has been tightening its links with fellow organisations in Geneva's vibrant international community.

Neutron Time-Of-Flight facility: n\_TOF

# The n\_TOF project

Istituto Nazionale di Fisica Nucleare

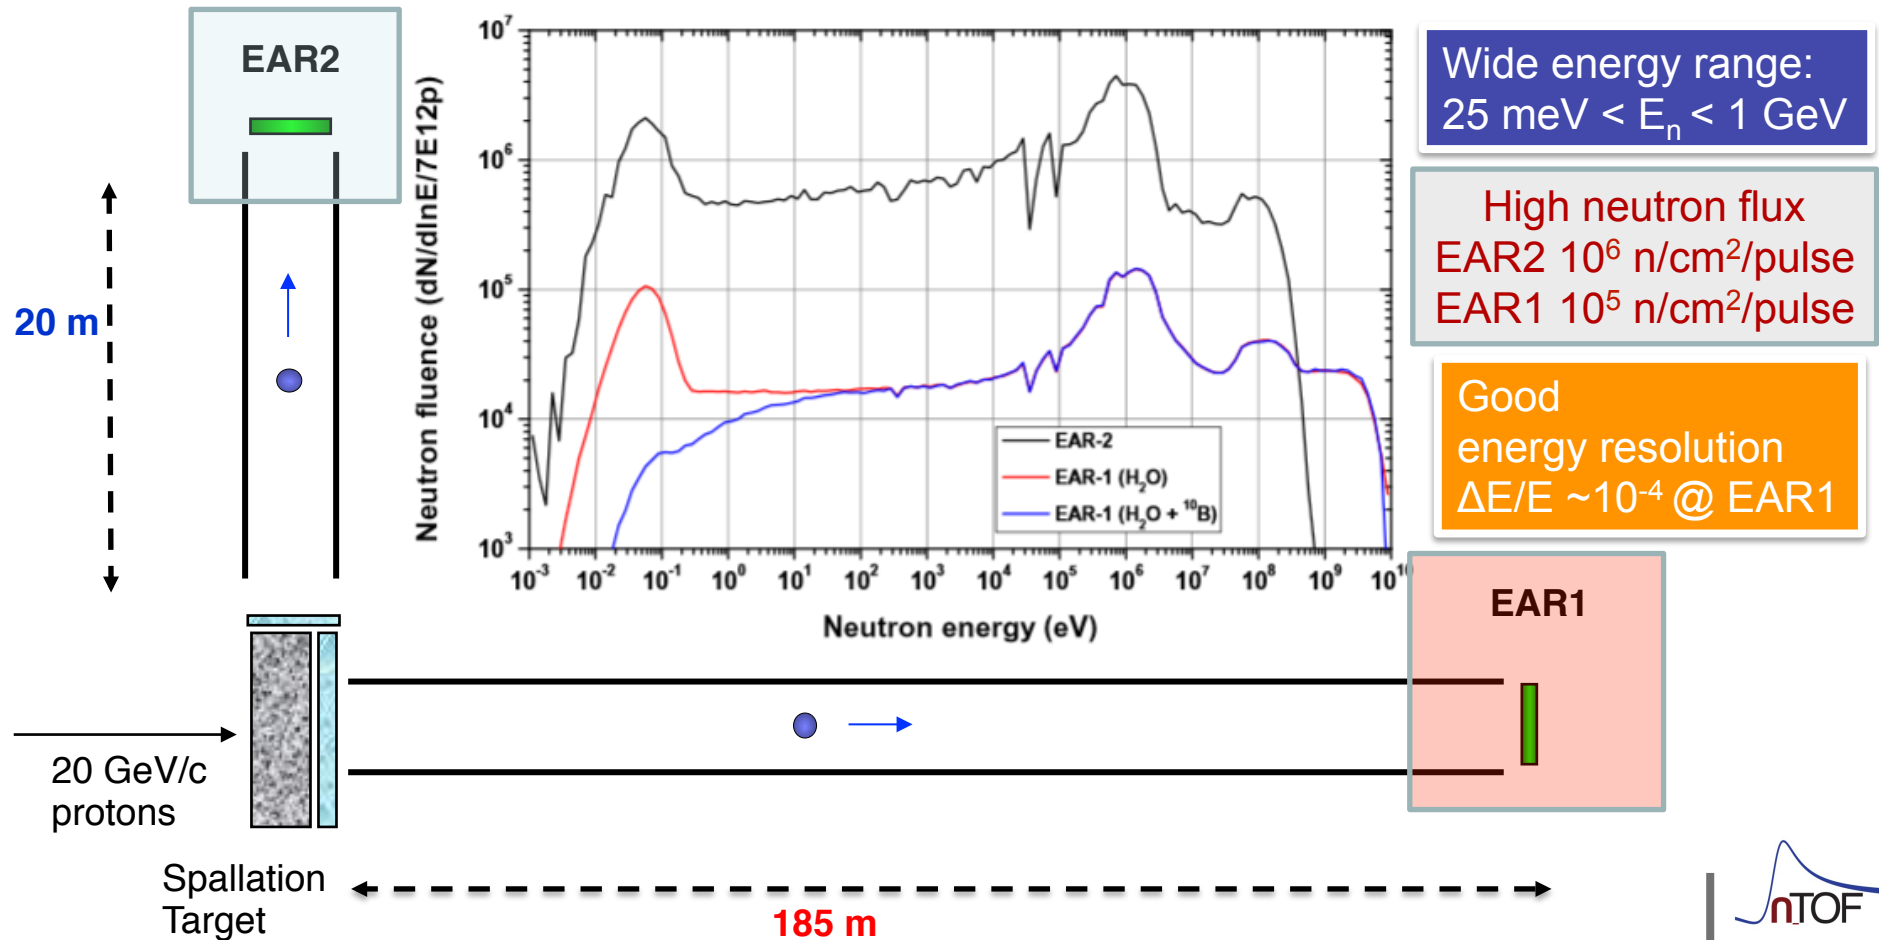

**n\_TOF** is a spallation neutron source based on **20 GeV/c protons** from the CERN PS hitting a **Pb block** (~300 neutrons per proton and  $\sim 7 \times 10^{12}$  ppp).  
Experimental area at **185 m** and **18.5 m**.

# The n\_TOF project

The advance of n\_TOF are a direct consequence of the characteristics of the **PS proton beam: high energy, high peak current, low duty cycle.**

## Detectors: radiative capture

Capture reactions are measured by detecting  $\gamma$ -rays emitted in the de-excitation process. **Two different systems**, to minimize different types of background

## Detectors: fission

Several systems have been used for detecting fission fragments.  
The main **problem** in fission measurements is the **background** due to  $\alpha$ -decay.

**Parallel Plate Avalanche Counters (PPAC)**

- Fission fragments detected **in coincidence**
- Very good rejection of  $\alpha$ -background

**Micromegas chamber**

- low-noise, high-gain, radiation-hard detector

## Detectors: (n, p) and (n, $\alpha$ ) reactions

Gas and solid state detectors are used for detecting charged particles, depending on the energy region of interest and the Q-value of the reaction

Silicon detectors  
Silicon sandwich  
Diamond detector  
 $\Delta E$ -E Telescopes

#### Abstract

The analysis of the neutron flux of n\_TOF (in EAR1) revealed an anomaly in the 10-30 keV neutron energy range. While the flux extracted on the basis of the  $^6\text{Li}(n, t)^4\text{He}$  and  $^{10}\text{B}(n, \alpha)^7\text{Li}$  reactions mostly agreed with each other and with the results of FLUKA simulations of the neutron beam, the one based on the  $^{235}\text{U}(n, f)$  reaction was found to be systematically lower, independently of the detection system used. A possible explanation is that the  $^{235}\text{U}(n, f)$  cross-section in that energy region, where in principle should be known with an uncertainty of 1%, may be systematically overestimated. Such a finding, which has a negligible influence on thermal reactors, would be important for future fast critical or subcritical reactors. Furthermore, its interest is more general, since the  $^{235}\text{U}(n, f)$  reaction is often used at that energy to determine the neutron flux, or as reference in measurements of fission cross section of other actinides. We propose to perform a high-accuracy, high-resolution measurement of the  $^{235}\text{U}(n, f)$  cross section in EAR1@n\_TOF, to clarify this issue.

Comment

Au-197 is used as standard for most astrophysical cross section measurements. Unfortunately, it is at the moment only a standard in the thermal region and between E(n)= 200 keV and 2.8 MeV (au197). Recent measurements at nTOF (CL11, CM10) and GELINA (MBD14) show a discrepancy of about 5% to the previously used standard value at kT= 30 keV from RaK88 and Mac82e.

The new recommended standard cross section for the astrophysical energy region was derived between kT= 5 and 50 keV by the weighted average of the GELINA measurement of MBD14 and the nTOF measurement of CL11,CM10. The uncertainty in this energy range was taken from MBD14. For the energies between kT= 60-100 keV we used the average of the recent libraries (jeff32, jendl40, endfb71) and the uncertainty from the standard deviation given in jeff32 and endfb71.

The previous standard value used for activations with the Li-7(p,n)Be-7 reaction at E(p)= 1912 keV was 586 (9) mb, the so-called "Ratynski value" (RaK88). At this energy the neutrons are collimated in a forward cone of 120 degree opening angle and resemble a quasi-stellar neutron spectrum of kT= 25 keV. With the new results this value would change to 632 (9) mb.

**1. CONSTRAINTS for  $^{22}\text{Ne}(\alpha, n)$   $^{25}\text{Mg}$ :** it is one of the most important **neutron source in Red Giant stars**. Its reaction rate is very **uncertain** because of the **poorly known property of the states in  $^{26}\text{Mg}$** . From neutron measurements the  **$J^\pi$  of  $^{26}\text{Mg}$  states can be deduced**.

**2. NEUTRON POISON:**  $^{25,26}\text{Mg}$  are the most important **neutron poisons** due to neutron capture on Mg stable isotopes in competition with neutron capture on  $^{56}\text{Fe}$  (the basic s-process seed for the production of heavy isotopes).

## Constraints for the $^{22}\text{Ne}(\alpha, n)^{25}\text{Mg}$ reaction

Element	Spin/ parity
$^{22}\text{Ne}$	$0^+$
$^4\text{He}$	$0^+$

Only natural-parity states in  $^{26}\text{Mg}$  can participate in the  $^{22}\text{Ne}(\alpha, n)^{25}\text{Mg}$  reaction

$$\vec{J} = \vec{I} + \vec{i} + \vec{\ell}$$

$$\vec{J} = \vec{0} + \vec{\ell}$$

$$\pi = (-1)^\ell$$

$$J^\pi = 0^+, 1^-, 2^+, 3^-, 4^+ \dots$$

## Constraints for the $^{22}\text{Ne}(\alpha, n)^{25}\text{Mg}$ reaction

Element	Spin/parity
$^{25}\text{Mg}$	$5/2^+$
neutron	$1/2^+$

$$\vec{J} = \vec{I} + \vec{i} + \vec{\ell}$$

$$\vec{J} = 2 + \vec{\ell} \quad \vec{J} = 3 + \vec{\ell}$$

s-wave  $\rightarrow J^\pi = \underline{2}^+, 3^+$

p-wave  $\rightarrow J^\pi = \underline{1}^-, 2^-, \underline{3}^-, 4^-$

d-wave  $\rightarrow J^\pi = \underline{0}^+, 1^+, \underline{2}^+, 3^+, \underline{4}^+, 5^+$

**States in  $^{26}\text{Mg}$  populated by  $^{25}\text{Mg}+n$  reaction**

(The n\_TOF Collaboration ([www.cern.ch/ntof](http://www.cern.ch/ntof)))

“One of the most accurate measurements and analysis procedure”

## GEANT4 simulation of the n\_TOF neutron source

**GEOMETRY:** spallation target, coolant and moderator systems separated, the support structures and the concrete pit in which it is mounted.

**2 SCORING PLANES:** towards EAR1 and EAR2 (at the entrance of the beam pipe).

**MODERATOR:** borated water is made with 4.2% in weight of  $H_3BO_3$ , with a  $^{10}B$  enrichment of 90%.

## GEANT4 simulation of the n\_TOF neutron source

## GEANT4 simulation of the n\_TOF neutron source

## Resolution function, impact on resonances

$$\lambda = vt_{\text{mod}}$$

**Equivalent  
distance**

**Velocity at the  
scoring plane**

**Time spent by the  
neutron inside the  
target assembly**

## Resolution function, impact on resonances

Well-known neutron resonances of  $^{197}\text{Au}$  and  $^{56}\text{Fe}$

The stochastic process of **moderation** inside the neutron-producing target causes a **broadening of the energy** distribution of neutrons reaching the experimental area at a given TOF.

## Beam Profile

Oliver Aberle (oliver.aberle@cern.ch)

**Abstract:** We propose to measure the neutron capture cross-section of  $^{155}\text{Gd}$  and  $^{157}\text{Gd}$  from thermal to 1 MeV neutron energy. The main motivation is related to the need of accurate data for applications to nuclear reactors, but new data could also be useful for recent developments in Neutron Capture Therapy, and for new detector concepts in neutrino research. The measurement should be performed in EAR-1 with cutting edge  $\text{C}_6\text{D}_6$  detectors specifically designed for n\_TOF. Since the cross section of these two isotopes changes by orders of magnitude as a function of neutron energy, two highly-enriched samples for each isotope will be measured: a very thin one up to 100 meV, and a thicker one for cross section determination above 100 meV.

EUROPEAN ORGANIZATION FOR NUCLEAR RESEARCH

Proposal to the ISOLDE and Neutron Time-of-Flight Committee

Measurement of the neutron capture cross section of gadolinium even isotopes relevant to Nuclear Astrophysics

May 5, 2015

**Spokespersons:**

Cristian Massimi (massimi@bo.infn.it) and Federica Mingrone (mingrone@bo.infn.it)

**Technical coordinator:**

Oliver Aberle (oliver.aberle@cern.ch)

**Abstract:**

We propose to measure the neutron capture cross-section of the stable isotopes  $^{152}\text{Gd}$ ,  $^{154}\text{Gd}$ ,  $^{156}\text{Gd}$ ,  $^{158}\text{Gd}$  and  $^{160}\text{Gd}$ . This experiment aims at the improvement of existing data of interest for nuclear astrophysics. The measurement will be carried out under similar conditions of previous measurements successfully completed at n\_TOF with an optimized detection set-up: a cutting edge detector especially designed for accurate  $(n,\gamma)$  measurement will be exploited in combination with a series of isotopically enriched samples. Concerning the correction related to isotopic impurities, we count on taking advantage of the result of the measurement on the  $^{155}\text{Gd}(n,\gamma)$  and  $^{157}\text{Gd}(n,\gamma)$ , subject of a different proposal.

# Th/U fuel cycle

Il  ${}^{232}\text{Th}$  è l'isotopo **fertile**: a seguito della cattura neutronica (e successivi decadimenti  $\beta$ ), produce il  ${}^{233}\text{U}$ , **isotopo fissile**.

Necessarie sezioni d'urto accurate su  ${}^{232}\text{Th}(n,\gamma)$  e  ${}^{233}\text{U}(n,f)$ , ma non solo.

Importante le sezioni d'urto di cattura e fissione del  ${}^{233}\text{Pa}$ , molto difficile da misurare direttamente.

# s- and r- process

## Stellar nucleosynthesis (s-, r-process)

## Compound neutron-nucleus reactions

## The R-matrix formalism

### The Breit-Wigner Single Level approximation:

total cross section:

$$\sigma_c = \pi \lambda_c^2 g_c \left( 4 \sin^2 \phi_c + \frac{\Gamma_\lambda \Gamma_{\lambda c} \cos 2\phi_c + 2(E - E_\lambda - \Delta_\lambda) \Gamma_{\lambda c} \sin 2\phi_c}{(E - E_\lambda - \Delta_\lambda)^2 + \Gamma_\lambda^2/4} \right)$$

neutron channel:  $c = n$

only capture, scattering, fission:  $\Gamma_\lambda = \Gamma = \Gamma_n + \Gamma_\gamma + \Gamma_f$

other approximations:  $\ell = 0$      $\cos \phi_c = 1$      $\sin \phi_c = \rho = ka_c$      $\Delta_\lambda = 0$

total cross section:

$$\sigma_T(E) = \overbrace{4\pi R'^2}^{\text{potential}} + \pi \lambda^2 g \left( \frac{\overbrace{4\Gamma_n(E - E_0)R'/\lambda}^{\text{interference}} + \overbrace{\Gamma_n^2}^{\text{elastic}} + \overbrace{\Gamma_n\Gamma_\gamma}^{\text{capture}} + \overbrace{\Gamma_n\Gamma_f}^{\text{fission}}}{\underbrace{(E - E_0)^2 + (\Gamma_n + \Gamma_\gamma + \Gamma_f)^2/4}_{\text{total width}}} \right)$$

The flux was measured for each target, with **four** different systems based on  $^6\text{Li}$ ,  $^{10}\text{B}$  and  $^{235}\text{U}$ .

Measurements were repeated for the  $^{10}\text{B}$ -water moderator (the thermal peak in the flux is suppressed).

**The use of borated water** suppresses the 2.2 MeV g-rays from  $^1\text{H}(n,g)^2\text{H}$ . Background reduced by a factor of 10 in some energy regions!
