Wilson loop

In any gauge theory

$$W_{\mathcal{R}}[C] = \frac{1}{\dim_{\mathcal{R}}} \text{Tr}_{\mathcal{R}} \mathcal{P} e(i \oint_C A_{\mu} \dot{x}^{\mu} d\tau)$$

measures the phase of an external particle.

For a given theory the Wilson loop depends on

- ▶ The trajectory of the particle $C \rightarrow x^{\mu}(\tau)$
- ▶ The flavor/charge of the particle $\mathcal{R} \rightarrow$ gauge group repr.

There are a lot of interesting implications...

Wilson loop in $\mathcal{N} = 4$ SYM

- ▶ Vector supermultiplet $(A_\mu, \lambda_\alpha^a, \Phi^I)$;
- ▶ Free parameters: $g_{\text{YM}}, N \rightarrow$ 't Hooft coupling $\lambda = g_{\text{YM}}^2 N$.

The loops couple also the scalars:

$$W_{\mathcal{R}}[C] = \frac{1}{\dim_{\mathcal{R}}} \text{Tr}_{\mathcal{R}} \mathcal{P} \exp \oint_C d\tau (iA_\mu(x)\dot{x}^\mu(\tau) + \dot{y}_I(\tau)\Phi^I)$$

The scalar coupling must satisfy $\dot{x}^2 = \dot{y}^2 \rightarrow$ local SUSY

With a suitable choice of scalar coupling \rightarrow global SUSY

- ▶ Zarembo $\dot{y}_I = M_I^\mu \dot{x}_\mu \rightarrow \langle W \rangle = 1$ [K.Zarembo '02]
- ▶ DGRT $\dot{y}_I = -\dot{x}_\mu \sigma_i^{\mu\nu} x_\nu M_I^i \rightarrow$ loops on S^3
[N.Drukker, S.Giombi, R.Ricci, D.Trancanelli '07]

The number of preserved supercharges depends on the path $x_\mu(\tau)$

Wilson loop ABJ(M)

- ▶ (A_μ, ψ^I, C^I) in the bifundamental of the group $U(N) \times U(M)$;
- ▶ Free parameters: $\kappa, N, M \rightarrow$ 't Hooft coupling $\lambda_1 = \frac{N}{\kappa}$, $\lambda_2 = \frac{M}{\kappa}$.

The contours couple also the scalars and the fermions:

$$W_{\mathcal{R}}[C] = \frac{1}{\dim_{\mathcal{R}}} \text{Tr}_{\mathcal{R}} \left[\mathcal{P} \exp \left(-i \int_C d\tau \mathcal{L}(\tau) \right) \right]$$

the $U(N) \times U(M)$ gauge connection with the super-connection

$$\mathcal{L}(\tau) \equiv -i \begin{pmatrix} i\mathcal{A} & \sqrt{\frac{2\pi}{\kappa}} |\dot{x}| \eta_I \bar{\psi}^I \\ \sqrt{\frac{2\pi}{\kappa}} |\dot{x}| \psi_I \bar{\eta}^I & i\hat{\mathcal{A}} \end{pmatrix} \quad \text{with} \quad \begin{cases} \mathcal{A} \equiv A_\mu \dot{x}^\mu - \frac{2\pi i}{\kappa} |\dot{x}| M_J{}^I C_I \bar{C}^J \\ \hat{\mathcal{A}} \equiv \hat{A}_\mu \dot{x}^\mu - \frac{2\pi i}{\kappa} |\dot{x}| \hat{M}_J{}^I \bar{C}^J C_I, \end{cases}$$

belonging to the super-algebra of $U(N|M)$.

[N.Drukker, D.Trancanelli '10]

Cusp anomalous dimension Γ_{CUSP}

$$W \sim e^{-\log\left(\frac{L}{\epsilon}\right)\Gamma_{CUSP}(\lambda, \varphi)}$$

with L and ϵ the IR and UV cut-off

Supersymmetric configuration: $\varphi = 0$

- ▶ Universal cusp anomaly $\Gamma_{CUSP}(\lambda, \varphi) \xrightarrow[\varphi \rightarrow \infty]{\varphi \rightarrow i\varphi} \varphi \gamma_{CUSP}(\lambda)$
- ▶ $Q\bar{Q}$ -potential $\Gamma_{CUSP}(\lambda, \varphi) \xrightarrow{\varphi \rightarrow \pi} \frac{V(\lambda)}{\pi - \varphi}$
- ▶ Bremsstrahlung function $\Gamma_{CUSP}(\lambda, \varphi) \xrightarrow{\varphi \rightarrow 0} -\varphi^2 \mathcal{B}(\lambda)$

Deforming the observable

R-symmetry deformation $\vec{n} \cdot \vec{n}' = \cos \theta$

$$W \sim e^{-\log\left(\frac{L}{\epsilon}\right) \Gamma_{CUSP}(\lambda, \theta, \varphi)}$$

with $\Gamma_{CUSP}(\lambda, \theta, \varphi)$ the generalized cusp anomalous dimension

[N.Drukker, V.Forini '11] [D.Correa, J.Henn, J.Maldacena, A.Sever '12]

Supersymmetric configuration: $\varphi = \pm \theta$

It is possible to have exact result for the generalized cusp?

Bethe-Salpeter equation for generalized cusp in $\mathcal{N} = 4$ SYM

We study the scaling limit which selects only ladder diagrams

$$i\theta \rightarrow \infty, \quad \lambda \rightarrow 0 \quad \text{with} \quad \hat{\lambda} = \frac{\lambda e^{i\theta}}{4} \quad \text{finite.}$$

[Correa, Henn, Maldacena, Sever '12]

Ladder diagram resummation \rightarrow Bethe-Salpeter equation

$$F(S, T) = 1 + \int_0^S ds \int_0^T dt F(s, t) P(s, t)$$

Integral equation \rightarrow Schroedinger equation with potential depending on the integral kernel $P(s, t)$

The 1-d Schroedinger problem

It is convenient to think about the problem on the sphere ($s = e^\sigma$, $t = e^\tau$)

$$\partial_{\sigma'} \partial_{\tau'} F(\sigma', \tau') = P(\sigma', \tau') F(\sigma', \tau')$$

Defining $x = \tau' - \sigma'$ and $y = \tau' + \sigma'/2$ and making the ansatz $F = \sum_n e^{-E_n y} \Psi_n(x)$

$$\left[-\partial_x^2 - P(x, y) \right] \Psi(x) = -\frac{E^2}{4} \Psi(x)$$

when $T = S \rightarrow \infty$, F is governed by the lowest eigenvalue then

$$E_0 = -\Gamma_{\text{cusp}}$$

- ▶ The energy can be computed exactly for $\varphi = 0$
- ▶ For arbitrary φ the Schroedinger problem is not exactly solvable

$$\Gamma_{\text{cusp}} = -\frac{\sqrt{\hat{\lambda}}}{2\pi \cos \varphi/2} \quad \hat{\lambda} \gg 1 \quad \text{in agreement with AdS/CFT}$$

[Correa, Henn, Maldacena, Sever '12] [Henn, Huber '12]

A sketch of the NLO

[Henn, Huber '12]

Outline

Introduction

Cusp anomalous dimension in $\mathcal{N} = 4$ SYM

Cusp anomalous dimension in ABJ(M)

Conclusions

The ABJ(M) kernels

The ABJ scaling limit

$$i\theta \rightarrow \infty, \quad \lambda_{1,2} \rightarrow 0 \quad \text{with} \quad \hat{\lambda}_{1,2} = \frac{\lambda_{1,2} e^{i\theta}}{2} \quad \text{finite.}$$

At leading order the relevant contributions are

$$\begin{aligned} &= \int ds dt P^{(F)}(s, t) \\ &= \left(\frac{2\pi}{\kappa}\right) MN \frac{\Gamma\left(\frac{1}{2} - \epsilon\right)}{4\pi^{3/2-\epsilon}} (\mu L)^{2\epsilon} \frac{1}{\epsilon} \frac{\cos \frac{\theta}{2}}{\cos \frac{\varphi}{2}}. \end{aligned}$$

$$\begin{aligned} &= \int ds dt P^{(B)}(s, t) \\ &= - \left(\frac{2\pi}{\kappa}\right)^2 MN^2 \frac{\Gamma^2\left(\frac{1}{2} - \epsilon\right)}{16\pi^{3-2\epsilon}} (\mu L)^{4\epsilon} \cos^2 \frac{\theta}{2} \frac{1}{\epsilon} \frac{\varphi}{\sin \varphi}. \end{aligned}$$

Bethe-Salpeter equation for generalized cusp in ABJ(M) (I)

$$F(S, T) = \sqrt{N} + \int_0^S ds \int_0^T dt MNF(s, t)P^{(B)}(s, t) + \sqrt{MN}\hat{F}(s, t)P^{(F)}(s, t)$$

$$\hat{F}(S, T) = \sqrt{M} + \int_0^S ds \int_0^T dt \sqrt{MNF}(s, t)P^{(F)}(s, t) + MN\hat{F}(s, t)P^{(B)}(s, t).$$

$$\langle \mathcal{W}_\pm \rangle = \frac{\langle \mathcal{W}_\uparrow \rangle \pm \langle \mathcal{W}_\downarrow \rangle}{N \pm M} \quad \Rightarrow \quad \langle \mathcal{W}_\pm \rangle = \frac{\sqrt{NF} \pm \sqrt{M\hat{F}}}{N \pm M}$$

Bethe-Salpeter equation for generalized cusp in ABJ(M) (II)

We decouple the integral equations defining

$$\mathcal{H}(x, y) = F + \hat{F} = h(y)\psi_+(x) \quad \mathcal{K}(x, y) = F - \hat{F} = k(y)\psi_-(x)$$

Two SUSY-QM Schroedinger equations

$$(-\partial_x^2 + a^2 W^2(x) - aW'(x)) \psi_+(x) = E\psi_+(x)$$

$$(-\partial_x^2 + a^2 W^2(x) + aW'(x)) \psi_-(x) = \tilde{E}\psi_-(x)$$

$$h(y) = C_1 e^{2\sqrt{-E+\frac{a^2}{2}}y} + C_2 e^{-2\sqrt{-E+\frac{a^2}{2}}y}$$

$$k(y) = C_3 e^{2\sqrt{-\tilde{E}+\frac{a^2}{2}}y} + C_4 e^{-2\sqrt{-\tilde{E}+\frac{a^2}{2}}y}$$

Solving the equations we get

$$\langle \mathcal{W}_+ \rangle = \frac{(\sqrt{M} + \sqrt{N})^2}{2(M + N)} e^{\sqrt{2}a \log \frac{\Lambda_{UV}}{\Lambda_{IR}}} + \frac{(\sqrt{M} - \sqrt{N})^2}{2(M + N)} e^{-\sqrt{2}a \log \frac{\Lambda_{UV}}{\Lambda_{IR}}},$$

$$\langle \mathcal{W}_- \rangle = \frac{1}{2} e^{\sqrt{2}a \log \frac{\Lambda_{UV}}{\Lambda_{IR}}} + \frac{1}{2} e^{-\sqrt{2}a \log \frac{\Lambda_{UV}}{\Lambda_{IR}}}.$$

[M.Bonini, L.Grigoalo, M.P., D.Seminara '16]

Bethe-Salpeter equation for generalized cusp in ABJ(M) (III)

The straight-line case ($\varphi = 0$) is exactly solvable with $\epsilon \neq 0$

$$\square \mathcal{H}(x', y') = \left[\vec{\nabla} W(x', y') \cdot \vec{\nabla} W(x', y') - \square W(x', y') \right] \mathcal{H}(x', y'),$$

$$\square \mathcal{K}(x', y') = \left[\vec{\nabla} W(x', y') \cdot \vec{\nabla} W(x', y') + \square W(x', y') \right] \mathcal{K}(x', y'),$$

with

$$W(x', y') = \frac{2^{\epsilon-1/2} a_\epsilon}{\epsilon} e^{\epsilon y'} \cos^{2\epsilon} \frac{x'}{2}, \quad a_\epsilon = \sqrt{\hat{\lambda}_1 \hat{\lambda}_2} \frac{\Gamma(1/2 - \epsilon) (\mu L)^{2\epsilon}}{(2\pi)^{1/2-\epsilon}}.$$

Solving the equations we get

$$\langle \mathcal{W}_+^{\varphi=0} \rangle = \frac{(\sqrt{M} + \sqrt{N})^2}{2(M+N)} e^{-\frac{2^{\epsilon-1/2}}{\epsilon} a_\epsilon} + \frac{(\sqrt{M} - \sqrt{N})^2}{2(M+N)} e^{\frac{2^{\epsilon-1/2}}{\epsilon} a_\epsilon},$$

$$\langle \mathcal{W}_-^{\varphi=0} \rangle = \frac{1}{2} e^{-\frac{2^{\epsilon-1/2}}{\epsilon} a_\epsilon} + \frac{1}{2} e^{\frac{2^{\epsilon-1/2}}{\epsilon} a_\epsilon}.$$

[M.Bonini, L.Griguolo, M.P., D.Seminara '16]

The mixing matrix and the cusp anomaly

The two operators mix ($a, b = \pm$)

$$\mathcal{W}_a^B = \tilde{Z}_{ab} \mathcal{W}_b^R, \quad \tilde{Z}_{ab} = (Z_{\text{open}} \tilde{Z}_{\text{cusp}})_{ab} \xrightarrow{i\theta \rightarrow \infty} (\tilde{Z}_{\text{cusp}})_{ab}$$

the cusp anomalous dimension is defined by

$$(\Gamma_{\text{cusp}})_{ab} = \left[\mu \frac{\partial}{\partial \mu} \log \tilde{Z}_{\text{cusp}} \right]_{ab}.$$

Thus we have 2 cusp anomalous dimensions for $\varphi = 0$

$$\Gamma_{\text{cusp}}^{(1)} = -\Gamma_{\text{cusp}}^{(2)} = -\sqrt{\hat{\lambda}_1 \hat{\lambda}_2}$$

and the same for $\varphi \neq 0$

$$\Gamma_{\text{cusp}}^{(1)}(\varphi) = -\Gamma_{\text{cusp}}^{(2)}(\varphi) = -\frac{\sqrt{\hat{\lambda}_1 \hat{\lambda}_2}}{\cos \frac{\varphi}{2}}$$

In the "strong coupling" limit \Rightarrow no match with the $\sqrt{\hat{\lambda}}$ behavior of ST

The limits do not commute

$$\lambda \rightarrow 0, i\theta \rightarrow \infty + \hat{\lambda} \rightarrow \infty \neq \lambda \rightarrow \infty + i\theta \rightarrow \infty$$

Outline

Introduction

Cusp anomalous dimension in $\mathcal{N} = 4$ SYM

Cusp anomalous dimension in ABJ(M)

Conclusions

Conclusions and Outlook

Conclusions

- ▶ Using the BS resummation approach we have computed the VEV's for the traced and supertraced operator;
- ▶ We have extracted the two cusp anomalous dimensions from the VEV's noticing that the two operators mix;
- ▶ We propose a new double exponentiation for the cusped WL;
- ▶ We argue that the disagreement with the AdS/CFT prediction is due to the fact that the scaling limit does not commute with the strong-coupling limit.

Outlook

- ▶ To check the double exponentiation using PT;
- ▶ Study the mixing problem relaxing the scaling limit;
- ▶ Compute the NLO kernels and perform Bethe-Salpeter resummation.

NLO kernel
