INFN Torino

## First question: where to run

- Goal is to produce impactful publications as soon as possible
- Existing data sets at $\Upsilon(4 \mathrm{~S}, 5 \mathrm{~S})$ are too large
- Below $\mathrm{r}(4 \mathrm{~S})$

■ $\Upsilon(3 S)$ offers greatest access to lower bottomonium states

- Scan for direct production of $\Upsilon\left(n^{3} D_{1}\right)$ states
- Above r(5S)
- Scans have been done by both BaBar and Belle
- $\sim 6 \mathrm{fb}^{-1}$ accumulated by Belle at the $\Upsilon(6 \mathrm{~S})$

## First question: where to run

## Boundary conditions

- Goals of Phase 2

■ Machine study for settings to reach high luminosity

- Understand beam background for safe VXD installation
- Establish conditions for stable machine operation
- Reach target luminosity of $\sim 1 \times 10^{34} \mathrm{~cm}^{-2} \mathrm{~s}^{-1}$
- Phase 2 Operating Conditions

■ $\sim 4-5 \mathrm{mos}$. of machine studies, $\sim 1-2 \mathrm{mos}$. physics
Energy spread assumed to be $\sim 5 \mathrm{MeV}$ (similar to Belle)

- Maximum possible energy 11.06-11.25 GeV
- Stable operation close to $\Upsilon(4 \mathrm{~S})$ strongly preferred
- Large uncertainty on Phase 2 luminosity ( $20 \pm 20 \mathrm{fb}^{-1}$ )
- Phase 3
$\square$ Operate at nominal conditions ( $1+x 10^{34} \mathrm{~cm}^{-2} \mathrm{~s}^{-1}$ )
$\square$ Some combination of $\Upsilon(4 \mathrm{~S})$ and other energies?

## Performance: conversions

- Conversion photons: sacrifice efficiency for improved resolution
- Consider increased material to compensate for luminosity

## Performance: tracking

- $\Upsilon(3 S) \rightarrow \pi^{+} \pi^{-} \Upsilon(1 S / 2 S) \rightarrow \mu^{+} \mu^{-}$MC (50/50 split)
- Impact of lack of VXD: $\Upsilon(3 S) \rightarrow \pi^{+} \pi^{-} \Upsilon(2 S)$ not feasible
- $\Upsilon(\mathrm{nS}) \rightarrow \mu \mu$ mass resolution affected as well

Upsilon3S_Mrecoil

$\mathrm{m}(\Upsilon(1 S, 2 S) \rightarrow \mu \mu)$

Minimum pion momentum

## Performance: photons

- Phase 2 material effects do not appear to be significant for ECL
- Photon energy for $\Upsilon(3 S) \rightarrow \gamma \chi_{\mathrm{b} 2}(2 \mathrm{P}) \rightarrow \gamma \Upsilon(1 \mathrm{~S} / 2 \mathrm{~S})\left(\mu^{+} \mu^{-}\right) \mathrm{MC}$

$\mathrm{E}_{\gamma}{ }^{*}(\mathrm{GeV})$

4th Belle-II Italian Meeting
R.Mussa, First Year Physics at Belle-II

## High energy scans

## BABAR :

PRL102:012001 (2009)
Ldt $=25 \mathrm{pb}^{-1}$ per point, $\mathrm{E}=10.54-11.2$; dE=5 MeV Total $3.3 \mathrm{fb}^{-1}$
$\mathrm{Rb}=\sigma(\mathrm{bb}) / \sigma(\mu \mu)$
Impressive match with prediction by Tornqvist PRL 53:878 (1984)

Tornqvist used Eichten's coupled channel model.

## CCC Model

- Updated model
o Physical masses for heavy flavor mesons
- Measured masses for quarkonium states
- Added features
o Include relativistic corrections - Tensor interaction
- Include EM current couplings to ${ }^{3} D_{1}$ states
- Some tuning
- Fit the leptonic width of $1 S(c c, b b)$ and $1 D(c c)$ states
- Allow some adjustment of resonance masses above threshold.

## Eichten 2008: rethinking at CCCM

The bottom threshold region is simple compared to the charm region:

Can ignore D states

- Direct coupling of EM current to $n^{3} D_{1}$ states is small.
- Negligible mixing between ${ }^{3} \mathrm{~S}_{1}$ and ${ }^{3} \mathrm{D}_{1}$ states.

Only the ground state $B$ mesons
are needed $\left(B, B^{*}, B_{s}, B_{s}{ }^{*}\right)$
Analysis includes the lowest seven ${ }^{3} S_{1}(b b)$ states and nine final heavy-light pair states.

Mass differences between $B_{u}$ and $B_{d}$ states can be ignored.

$$
m\left(B^{0}\right)-m\left(B^{+}\right)=0.37 \pm 0.24 \mathrm{MeV}
$$

## Eichten 2008: rethinking at CCCM

4th Belle-II Italian Meeting
R.Mussa, First Year Physics at Belle-II

## BELLE-I scans

- 61 points, 50 / pb, 10.75-11.05 GeV
- 16 points, 1 / fb, $10.63-11.02 \mathrm{GeV}$

Not just Rb analysis: also $\mathrm{Y} \pi \pi$ Exclude Ali's peak at 10.91

4th Belle-II Italian Meeting
R.Mussa, First Year Physics at Belle-II

## BELLE-II wishes

We may think to take $10 \mathrm{fb}^{-1}$ at 10.75 (where Rb collapses and $\mathrm{R}_{\mathrm{Y}}$ starts rising); not a scan, just stay there

4th Belle-II Italian Meeting

R.Mussa, First Year Physics at Belle-II

We may think to take $10 \mathrm{fb}^{-1}$ at 10.75 (where Rb collapses and $\mathrm{R}_{\mathrm{Y}}$ starts rising) ... and $10 \mathrm{fb}^{-1}$ at 10.65 (where Rb shows a dip, just above the $B^{*} B^{*}$ threshold)

Study these channels: $\mathrm{BB}, \mathrm{B}^{*} \mathrm{~B}, \mathrm{~B}^{*} \mathrm{~B}^{*}, \mathrm{Y} \pi \pi, \mathrm{Y} \eta$ at $10.65,10.75$
4th Belle-II Italian Meeting
R.Mussa, First Year Physics at Belle-II

## CLEO-c scans in Charmonium region

BELLE, BABAR (ISR) and CLEO-C have scanned the charmonium region deconvoluting all 2,3,4 body contributions. The D*D* threshold region at $\mathrm{Ecm}=4015 \mathrm{MeV}$ is particularly interesting.

## CCCM in Charmonium region

© Model of Dubynskiy \& Voloshin [ Mod. Phys. Lett. A21, 2779 (2006)]

- Express exclusive channels in terms of dimensionless $R_{k}$
- Parametrize $R_{k}$ in terms of expected threshold behavior \& relative production rates in the presence of a $\psi(4040)$

4th Belle-II Italian Meeting
R.Mussa, First Year Physics at Belle-II

9Fit to CLEO data: one large deviation near D*D* threshold OThis model needs interference with a new narrow resonance at $\mathrm{E}_{\mathrm{cm}}=4015 \mathrm{MeV}$ to explain dip in DD

- Preliminary evidence for $\Upsilon(6 S) \rightarrow \pi \pi h_{b}(n P)$, via $\pi Z_{b}{ }^{ \pm}(106 X X)$ decay

- Resonance structure of $\Upsilon(6 \mathrm{~S}) \rightarrow \pi \pi \Upsilon(\mathrm{pS})$ decays not fully studied

## Conclusioni

Partiamo dal presupposto che $\mathrm{Ldt}<40 \mathrm{fb}^{-1}$
Risoluzione energia dei fotoni non eccessiva
Molto inefficienti su low momentum tracks.
$\mathrm{Y}(3 S) \mathrm{e}^{\prime}$ la best option per $\sim 150 \mathrm{fb}^{-1}$ ed e' preferibile farla in fase 3
Un test run sul picco della $Y(6 S)$, anche di soli $40 \mathrm{fb}^{-1}$, ci darebbe 10x gli eventi presi in Belle-I. SE i macchinisti sono disposti ad andare cosi in alto, questo e' il punto piu' interessante.

Le zone dei due dip in $\mathrm{Rb}, 10.65+10.75 \mathrm{GeV}$, si prestano a studi sui coupled channels effects.

Physics with $600 \mathrm{M} \mathrm{Y(3S):}$

## - The $\eta, \pi$ transitions

- Hindered E1 transitions
- M1 transitions to $\eta_{b}(1,2 S)$
- D waves
$-\mathrm{Y}(3 \mathrm{~S}) \rightarrow \pi \pi \mathrm{Y}(1,2 S)$
- Antinuclei from Y(3S)

## Target Ldt: $150 \mathrm{fb}^{-1}$

All during BEAST-2 Phase? Or
50 during BEAST-2, and 100 while taking first $Y(4 S)$ data ( $3 \mathrm{ab}^{-1}$ )

Alternative scenarios:
Running at $\Upsilon(4 \mathrm{~S})$ and continuum point Running at $\Upsilon(6 \mathrm{~S}), 30 \mathrm{fb}^{-1}=6 \times$ Belle-I

Scan of $Y\left(1^{3} D_{1}\right), 7 \times 2 \mathrm{fb}^{-1}$ points, 14 total Scan of $\Upsilon\left(2^{3} D_{1}\right), 10 \times 1.5 \mathrm{fb}^{-1}$ points , 15 total

Can we do them during BEAST-2 Phase?
Luminosity ramp-up scenarios:

- at $\mathrm{L} 1=1 \times 10^{34}, 0.75 \mathrm{fb}^{-1} /$ day

How many days to reach L1?
How long will Phase-II last?

## The $\pi \tau / \eta$ transitions: TH vs EXP

## Hadron transition puzzle: solved?

From Eichten's talk at Krakow

- Above heavy flavor production threshold the usual QCDME fails.
- The transitions rate are much larger than expected.
- The factorization assumption fails. Heavy quark and light hadronic dynamics interact strongly due to heavy flavor meson pair (four quark) contributions to the quarkonium wavefunctions. Magnetic transitions not suppressed.
- A new mechanism for hadronic transitions is required.
- A new mechanism, in which the dynamics is factored differently, is purposed.
- It requires an intermediate state containing two narrow heavy-light mesons nearby and near threshold ( $v$-> zero). This is the factor. Other light hadrons may be present or not.
- The production of this state from the initial state is calculated using familiar strong dynamics of coupled channels.
- The evolution of this threshold system into the final quarkonium state and light hadrons requires a new threshold dynamics.
- HQS as well as the usual $\operatorname{SU}(3)$ and chiral symmetry expectations are recovered.
- Resolves the puzzles in $n$ transitions.

## Hadron transitions: a new paradigm?

From Eichten's talk at Krakow

For lower states, QCDME works:
$R_{Q \bar{Q}}(n \rightarrow m) \equiv \frac{\Gamma\left(n^{3} S_{1} \rightarrow m^{3} S_{1}+\eta\right)}{\Gamma\left(n^{3} S_{1} \rightarrow m^{3} S_{1}+\pi^{+} \pi^{-}\right)}:$

| Ratio | theory | experiment |
| :--- | :--- | :--- |
| $R^{c \bar{c}}(2 \rightarrow 1)$ | $3.29 \times 10^{-3}$ | $9.78 \times 10^{-2}$ |
| $R^{b \bar{b}}(2 \rightarrow 1)$ | $1.16 \times 10^{-3}$ | $1.16 \times 10^{-3}$ |
| $R^{b \bar{b}}(3 \rightarrow 1)$ | $4.57 \times 10^{-3}$ | $<4.13 \times 10^{-3}$ |
| $R^{b \bar{b}}(4 \rightarrow 1)$ | $2.23 \times 10^{-3}$ | 2.45 |
| $R^{b \bar{b}}(4 \rightarrow 2)$ | $5.28 \times 10^{-4}$ |  |

~ 30 > theory sets $C_{3} / C_{1}=0.143 \pm 0.024$ related to $\pi \pi$ suppression ~ 1000 > theory
$2 \mathrm{M}\left(\mathrm{D}^{0}\right)-\mathrm{M}\left(\psi^{\prime}\right)=53.11 \mathrm{MeV} / \mathrm{c}^{2} \quad 2 \mathrm{M}\left(\mathrm{B}^{0}\right)-\mathrm{M}(\Upsilon 3 S)=204 \mathrm{MeV} / \mathrm{c}^{2}$
$2 \mathrm{M}\left(\mathrm{D}^{+}\right)-\mathrm{M}\left(\psi^{\prime}\right)=43.57 \mathrm{MeV} / \mathrm{c}^{2} \quad 2 \mathrm{M}\left(\mathrm{B}^{+}\right)-\mathrm{M}(\mathrm{Y} 3 \mathrm{~S})=204 \mathrm{MeV} / \mathrm{c}^{2}$
$2 \mathrm{M}\left(\mathrm{D}_{\mathrm{s}}\right)-\mathrm{M}\left(\psi^{\prime}\right)=250.5 \mathrm{MeV} / \mathrm{c}^{2} \quad 2 \mathrm{M}\left(\mathrm{B}_{\mathrm{s}}\right)-\mathrm{M}(\Upsilon 3 \mathrm{~S})=378 \mathrm{MeV} / \mathrm{c}^{2}$
Large enhancement of $\psi^{\prime} \rightarrow \eta \psi$ explained by the proximity of the $D \bar{D}, D_{s} \bar{D}_{\bar{s}}$ thresholds.
Large isospin violation in $\psi^{\prime} \rightarrow \pi h_{c}$ due to the large $\mathrm{D}^{0}-\mathrm{D}^{+}$mass difference
In bottomonium, degenerate $\mathrm{B}^{0} \overline{\mathrm{~B}}^{0} / \mathrm{B}^{+} \mathrm{B}^{-}$threshold $\rightarrow$ no isospin violation
The eta transition $3 S$ to 1 S is still in the ballpark: wavefunction overlaps can suppress is, like it happens in hindered E1 transitions. We ought to measure it, and (precisely) the E1 hindered transitions from 3S to 1P states.

## The $\eta$ transitions

Testing QCD multipole expansion In low mass region:
$\mathrm{Y}^{\prime} \rightarrow \eta \mathrm{Y}: \mathrm{M} 2^{\star} \mathrm{E} 1+\mathrm{M} 1^{*} \mathrm{M} 1$
$\mathrm{Y}^{\prime} \rightarrow \pi \pi Y: E 1 * E 1$
$\left(\mathrm{Y}^{\prime} \rightarrow \eta \mathrm{Y}\right) /\left(\mathrm{Y}^{\prime} \rightarrow \pi \pi \mathrm{Y}\right) \sim\left(\Lambda_{\mathrm{QCD}} / \mathrm{m}_{\mathrm{b}}\right)^{2}$
Three more transitions should be visible from $Y(3 S)$ but experimental limits, wheie250 available, are below theory expectations:
$-\mathrm{B}(\mathrm{Y}(3 S) \rightarrow \eta \mathrm{Y}(1 S)) \quad$ theory: $5-10 \times 10^{-4}$ BaBarprd84,42003(2011) $<1 \times 10^{-4}$

- $\mathrm{Y}(1 \mathrm{D}) \rightarrow \eta \mathrm{Y}(1 S)$

Voloshin: PLB 562, 68(2003)
QCD Axial Anomaly should enhance $Y(1 D) \wedge 9500$ $\eta \mathrm{Y}(1 \mathrm{~S})$ with respect to $\mathrm{Y}(1 \mathrm{D})^{\wedge} \pi \pi \mathrm{Y}(1 \mathrm{~S})$ : no quantitative estimates available.
$-\mathrm{B}\left(\chi_{\mathrm{bo}}(2 \mathrm{P}) \rightarrow \eta \eta_{\mathrm{b}}\right) \sim$ few $10^{-3}$ (S-wave)
Voloshin: Mod.Phys.Lett. A19, 2895(2004)
$\frac{\Gamma\left(\chi_{b 0}(2 P) \rightarrow \eta \eta_{b}\right)}{\Gamma\left(\chi_{b 0}(2 P) \rightarrow \gamma \Upsilon\right)} \approx \frac{\pi^{3}}{3 \alpha} \frac{p_{\eta} f_{\eta}^{2} m_{\eta}^{4}}{\omega_{\gamma}^{3} m_{b}^{2} \Delta^{2}} \approx 0.2\left(\frac{f_{\eta}}{0.16 \mathrm{GeV}}\right)^{2}\left(\frac{1 \mathrm{GeV}}{\Delta}\right)^{2}$

4th Belle-II Italian Meeting
R.Mussa, First Year Physics at Belle-II

## Phase 2 Detectors

- VXD BEAST assembly
- SVD, PXD ladders
- Dedicated background and environment sensors (see next page)
- Scintillators and PIN diodes around QCS
- Neutron detector in dock space

- Beam Exorcism for A STable Belle II
- Collection of radiation monitoring detectors used during beam commissioning stages (Phase 1 and Phase 2)
- Inner detector

■ One octant of PXD + SVD (integrated into Belle 2 DAQ)
FANGS, CLAWS, PLUME: 5 out of 8 remaining octants

- Designed to minimize amount of additional material
- Outer detector

- Nominal Belle II configuration
- Drift chamber (CDC), PID (TOP/ARICH), calorimeter (ECL), muons (KLM)
- Other
- "Dock space" has He-3 and TPCs for neutron detection
- Beampipe has $\sim 6 \mu \mathrm{~m}$ gold plating (compared to $10 \mu \mathrm{~m}$ for nominal)

## - VerteX Detector configuration

■ 2 PiXel Detector / 4 Silicon Vertex Detector ladders

- Similar to final Belle II vertex detector components
- Located at $\phi=0^{\circ}$
- Integrated into Belle II DAQ system

## - FE-I4 ATLAS Near Gamma Sensors

- Radiation-hard Si pixel detectors
- Located at $\phi=90^{\circ}, 180^{\circ}, 270^{\circ}$

- sCintillation Light And Waveform Sensors

■ Plastic scintillator with Si photomultipler readout

- Located at $\phi=135^{\circ}$ and $225^{\circ}$

- Pixelated Ladder with Ultra-low Material Embedding
- CMOS pixels on light support structure
- Complementary to CLAWS, same location
- Final orientation under study

## Neutron Detectors

- He-3 tubes and microTPCs in dock space
- TPCs image direction of incoming fast neutrons, but detected rate is low
- He-3 measure rate of thermal neutrons, which is high
