## Introduction

During the last few years, very intriguing observations appeared in charm and beauty baryon spectroscopy (Particle Data Group, 2008).

It would be interesting to discuss how successfully various models describe the masses of the observed baryons. The central problem of all studies on this subject is establishing the structure of new baryons within the quark model, in particular, of the cascade baryons with new flavors (see Ono_1978 - Ebert-Faustov-Galkin_2005 and references therein).

On the other hand, many characteristics of the baryons are successfully determined in the framework of QCD sum rules method \{loffe_1981\} (see Colangelo-Khodjamirian_2001 about this method). The main issue in the applications of sum rules is the choice of an interpolating current with the same quantum numbers of the corresponding baryon. In the present work, we discuss some interesting points changing considerably the usual way of constructing mass formulae for the heavy baryons either within the quark model or in the QCD sum rules method.

The plan of the report is as follows.
In section II, we discuss the problem of mixing of the baryon wave functions in the quark model Ono_1978.

Then the obtained results are used to construct wave functions of the baryons which are used to calculate masses and magnetic moments of the baryons. In the last section, we apply the same method to construct interpolating QCD currents and modify the sum rules.

In conclusion, we discuss our results

QCD\&Work 2010, International Workshop on Quantum Chromodynamics - Thery and Experiment
Mixing of the cascade baryons $\bar{\Xi}_{\mathrm{c}}, \bar{\Xi}_{\mathrm{c}}{ }^{`}$ in the quark model
Let us consider standard non-relativistic quark model (NRQM) wave functions of the charm cascade baryons $\bar{\Xi}_{c}$ 's of the $\operatorname{SU}(4) 20^{\circ}$ - plet, having in their content three different quarks $\mathbf{u}, \mathbf{d}, \mathbf{s}, \mathbf{c}$.

Upon reduction to $\operatorname{SU}(3)$ these baryons occur in the sum of sextet and triplet representations of $\operatorname{SU}(3)\left(20{ }_{4}=8_{3}+6_{3}+3_{3}+3_{3}\right)$. One can choose the wave functions of the $\wedge$ - like baryons $\bar{\Xi}_{c}$ with the quark content (usc) as
$\sqrt{6} B^{4}{ }_{[24]}=\sqrt{ } 6 \Xi_{c}([u s] c)=-c_{1} u_{1} s_{2}-u_{1} c_{1} s_{2}+s_{1} c_{1} u_{2}+c_{1} s_{1} u_{2}$
$\sqrt{6 B}{ }_{[23]}^{3}=\sqrt{ } 6 \Xi_{c}([u c] s)=+s_{1} u_{1} c_{2}+u_{1} s_{1} c_{2}-s_{1} c_{1} u_{2}-c_{1} s_{1} u_{2}$
$\sqrt{6} B^{1}{ }_{[21]}=\sqrt{6} \Xi_{c}([s c] u)=-s_{1} u_{1} c_{2}-u_{1} s_{1} c_{2}+s_{1} u_{1} s_{2}+u_{1} c_{1} s_{2}$
Here $\mathrm{q}_{1,2}$ means spin (up, down), respectively
Since the sum of these states is equal to zero, only two of the states are linearly independent. But any two of them are not orthogonal to each other, so we construct to every state three possible orthogonal combinations, corresponding to $\Sigma$ - like baryons:

QCD\&Work 2010, International Workshop on Quantum Chromodynamics - Thery and Experiment
$-\sqrt{6}\left(B^{1}{ }_{[21]}-B^{3}{ }_{[23]}\right)=2 \sqrt{3} \Xi^{\circ}{ }^{\circ}(\{u s\} c)=$
$=2 s_{1} u_{1} c_{2}+2 u_{1} s_{1} c_{2}-c_{1} u_{1} s_{2}-u_{1} c_{1} s_{2}-s_{1} c_{1} u_{2}-c_{1} s_{1} u_{2}$
$-\sqrt{6}\left(B^{4}{ }_{[24]}-B^{1}{ }_{[211]}\right)=2 \sqrt{ } 3 \Xi^{\circ} c(\{u c\} s)=$
$=2 c_{1} u_{1} s_{2}+2 u_{1} c_{1} s_{2}-s_{1} u_{1} c_{2}-u_{1} s_{1} c_{2}-s_{1} c_{1} u_{2}-c_{1} s_{1} u_{2}$
$\sqrt{6}\left(B^{4}{ }_{[24]}-B^{3}{ }_{[23]}\right)=2 \sqrt{ } 3 \Xi^{`} c(\{s c\} u)=$
$=2 c_{1} s_{1} u_{2}+2 s_{1} c_{1} u_{2}-s_{1} u_{1} c_{2}-u_{1} s_{1} c_{2}-s_{1} u_{1} s_{2}-u_{1} c_{1} s_{2}$

In principle, one can choose any pair of charm cascade baryons $\bar{\Xi}_{\mathrm{c},} \Xi_{{ }_{\mathrm{c}}}$.
Rotating the 1 st lines by $60^{\circ}$ one obtains the states of the 2nd line,
while rotating them by $120^{\circ}$ one obtains the states of the 3rd line.

Upon reduction of the $\operatorname{SU}(4) 20$ '- plet to the $\operatorname{SU}(3)$ multiplets along the values of charm, $\mathrm{C}=0,1,2$, one can see that
$\Lambda_{c}{ }^{+}([\mathrm{ud}] \mathrm{c}), \Xi_{\mathrm{c}}{ }^{+}([\mathrm{us}] \mathrm{c})$ and $\Xi_{\mathrm{c}}{ }^{0}([\mathrm{ds}] \mathrm{c})$ form the anti-triplet while $\Sigma_{\mathrm{c}}{ }^{+}(\{\mathrm{ud}\} \mathrm{c}), \Xi_{\mathrm{c}}{ }^{+}(\{\mathrm{us}\} \mathrm{c})$ and $\Xi_{\mathrm{c}}{ }^{\circ}(\{\mathrm{ds}\} \mathrm{c})$ enter the $\mathrm{SU}(3)$ sextet. quark content (usc).

Formally, masses of the $\bar{\Xi}_{c}, \bar{\Xi}_{c}$ ' are defined as
$M_{-}\left\{\Xi_{c}\right\}=<\bar{\Xi}_{c}|m| \Xi_{c}>, \quad M_{-}\left\{\bar{\Xi}_{c}{ }^{`}\right\}=<\Xi_{c}{ }^{`}|m| \Xi_{c}{ }^{`}>$
$\mathrm{M}\left(\Xi_{\mathrm{c}}([\mathrm{us}] \mathrm{c})\right)+3 \mathrm{M}\left(\Xi_{\mathrm{c}}{ }^{`}(\{\mathrm{us}\} \mathrm{c})\right)=2 \mathrm{M}\left(\Xi_{\mathrm{c}}([\mathrm{uc}] \mathrm{s})\right)+2 \mathrm{M}\left(\Xi_{\mathrm{c}}([\mathrm{cs}] \mathrm{u})\right)$,

Analogous relations exist for other choices of the cascade pair:

$$
M\left(\Xi_{\mathrm{c}}{ }^{`}(\{\mathrm{uc}\} \mathrm{s})\right)+3 \mathrm{M}\left(\Xi_{\mathrm{c}}([\mathrm{uc}] \mathrm{s})\right)=2 \mathrm{M}\left(\Xi_{\mathrm{c}}^{`}(\{\mathrm{us}\} \mathrm{c})\right)+2 \mathrm{M}\left(\Xi_{\mathrm{c}}^{`}(\{\mathrm{cs}\} \mathrm{u})\right),
$$

$$
\mathrm{M}\left(\Xi_{\mathrm{c}}([\mathrm{uc}] \mathrm{s})\right)+3 \mathrm{M}\left(\Xi_{\mathrm{c}}(\{\mathrm{uc}\} \mathrm{s})\right)=2 \mathrm{M}\left(\Xi_{\mathrm{c}}([\mathrm{us}] \mathrm{c})\right)+2 \mathrm{M}\left(\Xi_{\mathrm{c}}([\mathrm{cs}] \mathrm{u})\right)
$$

and
$M\left(\Xi_{c}{ }^{\prime}(\{c s\} u)\right)+3 M\left(\Xi_{c}([c s] u)\right)=2 M\left(\Xi_{c}^{`}(\{u c\} s)\right)+2 M\left(\Xi_{c}(\{u s\} c)\right)$,
$M\left(\Xi_{c}([c s] u)\right)+3 M\left(\Xi_{c}{ }_{c}(\{c s\} u)\right)=2 M\left(\Xi_{c}([u c] s)\right)+2 M\left(\Xi_{c}([u s] c)\right)$, In general, the off-diagonal terms are not zero.

Upon using group-theory relations
non-diagonal mass terms of the pair $\Xi_{c}(\{u c\} s)$ and $\Xi_{c}{ }^{`}(\{u c\} s)$ could be written in terms of the other states as
$\sqrt{3 M}\left(\Xi_{c}{ }^{`}(\{u s\} c) \Xi_{c}([u s] c)\right)=M(\equiv `(\{u c\} s))-M(\equiv `(\{c s\} u))=$
$=-M\left(\Xi_{\mathrm{c}}([\mathrm{uc}] \mathrm{s})\right)+\mathrm{M}\left(\bar{\Xi}_{\mathrm{c}}([\mathrm{cs}] \mathrm{u})\right)$,
and similarly for the other two pairs of the heavy cascade baryons:
$\sqrt{ } 3 \mathrm{M}\left(\Xi_{\mathrm{c}}{ }^{`}(\{\mathrm{uc}\} \mathrm{s}) \bar{\Xi}_{\mathrm{c}}([\mathrm{uc}] \mathrm{s})\right)=-\mathrm{M}\left(\bar{\Xi}_{\mathrm{c}}{ }^{`}(\{\mathrm{us}\} \mathrm{c})\right)+\mathrm{M}\left(\Xi_{\mathrm{c}}{ }^{`}(\{\mathrm{cs}\} \mathrm{u})\right)=$ $=\mathrm{M}\left(\Xi_{\mathrm{c}}([\mathrm{us}] \mathrm{c})\right)-\mathrm{M}\left(\Xi_{\mathrm{c}}([\mathrm{cs}] \mathrm{u})\right)$,
and
$\sqrt{ } 3 \mathrm{M}\left(\Xi_{\mathrm{c}}{ }^{`}(\{\mathrm{cs}\} \mathrm{u}), \Xi_{\mathrm{c}}([\mathrm{cs}] \mathrm{u})\right)=\mathrm{M}\left(\bar{\Xi}_{\mathrm{c}}{ }^{`}(\{\mathrm{us}\} c)\right)-\mathrm{M}\left(\bar{\Xi}_{\mathrm{c}}{ }^{`}(\{u c\} \mathrm{s})\right)=$
$=-\mathrm{M}\left(\Xi_{\mathrm{c}}([\mathrm{us}] \mathrm{c})\right)+\mathrm{M}\left(\Xi_{\mathrm{c}}([\mathrm{cs}] \mathrm{u})\right)$,

It is rather obvious that only for some particular choice of parameters the non-diagonal mass terms are equal to zero.

For example, isotopic invariance leads to the vanishing of these non-diagonal mass terms for the baryons $\Lambda([u d] h)$ and $\Sigma(\{u d\} h), \mathrm{h}=\mathrm{s}, \mathrm{c}, \mathrm{b}$.

QCD\&Work 2010, International Workshop on Quantum Chromodynamics - Thery and Experiment But what masses should we choose then to compare them with experiment? It is clear that the states of definite mass and their masses can be obtained by diagonalizing the mass matrix of the chosen model Ono_1978

$$
M\left(\Xi_{c}{ }^{`}\right) \quad M\left(\bar{\Xi}_{c} \bar{\Xi}_{c}{ }^{\prime}\right)
$$

$\mathrm{M}\left\{\mathrm{E}_{\mathrm{c}}\right\}=($

$$
M\left(\bar{\Xi}_{c} \Xi_{c}\right) \quad M\left(\bar{\Xi}_{c}\right)
$$

The corresponding secular equation yields the physical masses to be:

$$
2 \mathrm{M}\left(\bar{\Xi}_{c}^{1,2}\right)=\left(\mathrm{M}\left(\bar{\Xi}_{c}\right)+\mathrm{M}\left(\bar{\Xi}_{\mathrm{c}}{ }^{`}\right) \pm\left[\left(\mathrm{M}\left(\bar{\Xi}_{c}\right)-\mathrm{M}\left(\bar{\Xi}_{\mathrm{c}}{ }^{`}\right)\right)^{2}+4 \mathrm{M}_{-}\left(\bar{\Xi}_{\mathrm{c}} \bar{\Xi}_{\mathrm{c}}\right)^{2}\right]^{1 / 2},\right.
$$

where the off-diagonal elements are assumed to be equal,
i.e. $M\left(\bar{\Xi}_{c} \bar{\Xi}_{c}{ }^{\prime}\right)=M\left(\bar{\Xi}_{c}{ }^{`}{ }_{c}\right)$.
(Maybe the first time it was written by Jerold Franklin PR D. Recently this formula was written also by Lipkin et al. arXiv:0706.2163 (2007)

The values of these masses do not depend on which pair of $\bar{\Xi}_{c}, \quad \bar{\Xi}_{c}$ is chosen upon the mode of grouping quarks in "diquarks", since the sum $\left(M\left(\bar{\Xi}_{c}\right)+M \_\left(\bar{\Xi}_{c}{ }^{`}\right)\right.$ as well as the square root are invariant under rotations in the flavor space by $60^{\circ}$ and $120^{\circ}$.

To obtain the representation of the observable particles，the $\bar{\Xi}_{\mathrm{c}}, \bar{\Xi}_{\mathrm{c}}{ }^{`}$ should be rotated by some angle $\alpha$

三${ }_{c} \alpha=$ 三 $_{c}$ cos $\alpha+$ 三 $_{c} \sin \alpha$

三 $_{c \alpha}=-$ 三 $_{c} \sin \alpha+$ 末 $_{c} \cos \alpha$.

Requiring that the off－diagonal elements of the mass matrix for these newly defined states to be zero，the rotation angle $\alpha$ should be chosen as：
$\tan 2 \alpha=2<\bar{\Xi}_{c}{ }^{`}|m| \Xi_{c}>/\left[M\left(\Xi_{c}{ }^{`}\right)-M\left(\Xi_{c}\right)\right]$

It would be natural to define these diagonalized states as the physical ones． In this case a quark structure of the baryon（in the given model！） would be a superposition of the states $\Xi_{c}$ and $\Xi_{c}{ }^{`}$ ．

## Quark model for masses of new baryons

Let us apply the approach presented in the previous section to heavy baryons within the model of Ono_1978.

Already more than 20 years ago masses of heavy baryons with new quantum numbers were calculated within quark models (cf., e.g., Ono_1978 and Verma_1988).

It is of interest to note that the predictions on the masses of heavy baryons of these models are in surprisingly good agreement with the modern data. In the report the mass operator of Ono_1978 is used due to its simplicity and clearness:
$M_{B}=m_{0}+\sum_{i=1}^{3} m_{i}+x \sum_{i>j} \mathbf{S}_{\mathrm{i}} \mathbf{S}_{\mathrm{j}} /\left(\mathrm{m}_{\mathrm{i}} \mathrm{m}_{\mathrm{j}}\right)$,
where $\mathrm{m}_{0}$ is an overall constant, $\mathrm{m}_{0}=77 \mathrm{MeV}$, and $\mathrm{X}=22.0510^{-3} \mathrm{GeV}^{3}$; $\mathrm{S}_{\mathrm{q}}$ is the spin operator of the quark q .

Quark masses are taken from Ono_1978:
$m_{u}=m_{d}=336 \mathrm{MeV}, \quad \mathrm{m}_{\mathrm{s}}=510 \mathrm{MeV}, \quad \mathrm{m}_{\mathrm{c}}=1680 \mathrm{MeV}, \quad \mathrm{m}_{\mathrm{b}}=5000 \mathrm{MeV}$.

QCD\&Work 2010, International Workshop on Quantum Chromodynamics - Thery and Experiment

## Charm and beauty cascade hyperons

Masses of charm and beauty $\equiv$ and $\Omega$ baryons were calculated in Ono_1978 for particular quark combinations of baryons.

We have performed calculations for all the possible quark combinations in baryons with the same formula and put results into the Table 1.

As an example, the analysis for baryons with two different heavy quarks forming $\operatorname{SU}(3)$ triplets $\Xi^{`}{ }_{\mathrm{cb}}+, 0, \Omega{ }_{\mathrm{cb}}{ }^{0}$ and $\Xi_{\mathrm{cb}}{ }^{+, 0}, \Omega_{\mathrm{cb}}{ }^{0}$ is presented below. We would write in some detail calculations for the pair $\Xi_{c b}{ }^{+, 0}, \Xi^{`}{ }_{c b}^{+, 0}$.
(1) We begin with the quark content proposed in Ono_1978, i.e. let $\mathbf{b}$ be a single quark while the pair (uc) in (anti)symmetric state form a diquark For the diagonal elements of the mass matrix, we get
$\mathrm{M}_{\equiv c b}([c u] \mathrm{b})=\mathrm{m}_{0}+\mathrm{m}_{\mathrm{u}}+\mathrm{m}_{\mathrm{c}}+\mathrm{m}_{\mathrm{b}}+\chi(-3 / 4)\left(1 / \mathrm{m}_{\mathrm{u}} \mathrm{m}_{\mathrm{c}}\right)=$
$=7093+22.05(-3 / 4) 2.976^{2} / 5=7093-29.3=7063.7 \mathrm{MeV}$; (7064 Ono_1978)
$M_{\equiv}{ }^{\text {cb }}$ (\{cu\}b $)=m_{0}+m_{u}+m_{c}+m_{b}+(x / 4)\left(-2 / m_{u} m_{b}-2 / m_{c} m_{b}+1 / m_{u} m_{c}\right)=$ $=7093-6.5625-1.3125+9.7656=7093+1.891=7094.9 \mathrm{MeV}$ (7095 Ono_1978)
$\left[\mathrm{M}_{\equiv c b}([c u] \mathrm{b})+\mathrm{M}_{\equiv \mathrm{cc}}(\{\mathrm{ccu}\} \mathrm{b})\right] / 2=7079.3$;
$\left[\mathrm{M}_{\equiv \mathrm{cb}}([\mathrm{cu}] \mathrm{b})-\mathrm{M}_{\equiv \mathrm{ccb}}(\{\mathrm{cu}\} \mathrm{b})\right] / 2=-31.2$;
and the non diagonal matrix elements are:
$\sqrt{ } 3<\bar{\Xi}_{\mathrm{cb}}{ }^{`}|m| \bar{\Xi}_{\mathrm{cb}}>=(3 \mathrm{X} / 4)\left(1 / \mathrm{m}_{\mathrm{u}} \mathrm{m}_{\mathrm{b}}-1 / \mathrm{m}_{\mathrm{c}} \mathrm{m}_{\mathrm{b}}\right) \sim 7.9 \mathrm{MeV}$

Resolving the secular equation
$x_{1,2}=7079.3 \pm(1 / 2)\left[31.2^{2}+(3 / 4) 7.9^{2}\right]^{1 / 2}=7079.3 \pm 16.4$,
one obtains the mass eigenvalues as
$x_{1}=7095.7 \mathrm{MeV}, x_{2}=7063.5 \mathrm{MeV}$.
In order to go from the initial states $\Xi_{c b}{ }^{+, 0}, \Xi^{`}{ }_{c b}^{+, 0}$ to those with the masses $\mathrm{x}_{1,2}$ one should rotate them at the angle $\alpha=16.3^{0} / 2=8.15^{0}$, $\tan 2 \alpha=0.2924$.
(2) Now, let the quarks $\mathbf{c}$ and $\mathbf{b}$ form a diquark while the light quark $\mathbf{u}$ is the single one. In this case
$M_{\equiv c b}([c b] u)=m_{0}+m_{u}+m_{c}+m_{b}+X(-3 / 4)\left(1 / m_{b} m_{c}\right)=$
$=7093+22.05(-3 / 4) 2.796 / 25=7091 \mathrm{MeV}$,
$M_{\equiv c \mathrm{cb}}(\{c b\} u)=m_{0}+m_{u}+m_{c}+m_{b}+(x / 4)\left(-2 / m_{u} m_{c}-2 / m_{u} m_{b}+1 / m_{b} m_{c}\right)=$ $=7093-19.53-6.5625+0.65625=7093-25.43625=7067.6 \mathrm{MeV}$.
$\left[\mathrm{M}_{\equiv c b}([\mathrm{cb}] \mathrm{u})+\mathrm{M}_{\equiv} \mathrm{cc}(\{\mathrm{cb}\} \mathrm{u})\right] / 2=7079.3 ;$
$\left[\mathrm{M}_{\equiv c b}([\mathrm{cb}] \mathrm{u})-\mathrm{M}_{\equiv \mathrm{cc}}(\{\mathrm{cb}\} \mathrm{u})\right] / 2=23.4$.
The non-diagonal mass matrix element is now
$\sqrt{ } 3<\Xi_{c b}{ }^{`}(\{c b\} u)|m| \Xi_{c b}([c b] u)>=(3 \chi / 4)\left(1 / m_{c} m_{u}-1 / m_{b} m_{u}\right) \sim 19.4 \mathrm{MeV}$
wherefrom the eigenvalues are obtained as follows
$x_{1}=7095.2 \mathrm{MeV}, x_{2}=7062.8 \mathrm{MeV}$.
In order to go from the initial states $\Xi_{c b}^{+, 0}, \Xi_{c b}{ }^{+, 0}$ to those with the masses $X_{1,2}$ one should rotate them at the angle $\alpha=136.25^{\circ} / 2=68.13^{0}, \tan 2 \alpha=-0.9573$.
(3) Now quarks `u` and `b` form the diquark while charm quark ` $c$ ' is single. Then, the masses of the cascade baryons are given by:
$M_{\equiv c b}([u b] c)=m_{0}+m_{u}+m_{c}+m_{b}+X(-3 / 4)\left(1 / m_{b} m u\right)=$
$=7093+22.05(-3 / 4) 1 / 5 \quad 2.796=7093-9.9=7083.1 \mathrm{MeV}$;
$M_{\equiv ゙ c b}(\{u b\} c)=m_{0}+m_{u}+m_{c}+m_{b}+(x / 4)\left(-2 / m_{u} m_{c}-2 / m_{b} m_{c}+1 / m_{b} m_{u}\right)=$ =7093-27.7= 7075.3 MeV;
$\left[M_{\equiv c b}([u b] c)+M_{\equiv c b}(\{u b\} c)\right] / 2=7079.2 ;$
$\left[M_{\equiv c b}([u b] c)-M_{\equiv c b}(\{u b\} c)\right] / 2=7.7$.

The non-diagonal mass matrix element being
$\sqrt{3}<\bar{\Xi}_{\mathrm{cb}}{ }^{`}(\{\mathrm{ub}\} \mathrm{c})|\mathrm{m}| \bar{\Xi}_{\mathrm{cb}}([\mathrm{ub}] c)>=(3 \mathrm{x} / 4)\left(1 / \mathrm{m}_{\mathrm{u}} \mathrm{m}_{\mathrm{c}}-1 / \mathrm{m}_{\mathrm{b}} \mathrm{m}_{\mathrm{c}}\right) \sim 27.7 \mathrm{MeV}$ wherefrom the eigenvalues are obtained as follows
$x_{1}=7095.7 \mathrm{MeV}, x_{2}=7062.9 \mathrm{MeV}$.

In order to go from the initial states $\Xi_{c b}{ }^{+, 0}, \Xi^{`}{ }_{c b}^{+, 0}$ to those with the masses $x_{1,2}$ one should rotate them at the angle $\alpha=256 \cdot 5^{\circ} / 2=128 \cdot 25^{\circ}, \tan 2 \alpha=4.1539$.

Similar calculations are done also for other charm and beauty baryons and the results are presented in Table 1.

## Magnetic moments of the double-flavored baryons

From our analysis, it follows that the predictions on the mass of the physically observed baryons does not depend on the particular quark construction of the baryons in the given model.

However the wave function of the baryon with the diagonal mass matrix as well as all the characteristics of the baryon such as magnetic moments, weak decay constants, strong couplings and etc. depend upon these particular construction through the mixing angle $\alpha$.

As an application of our approach, let us consider the magnetic moments of the double-flavored baryons $\bar{\Xi}_{c b}{ }^{+}$and $\Xi^{`}{ }_{c b}{ }^{+}$. Magnetic moment of the baryon with the quark content $\bar{\Xi}_{\mathrm{cb}}{ }^{+}([\mathrm{cb}] \mathrm{u})$, which is used often in the modern works (cf., e.g., Faustov_2005), in the NRQM is equal to the u-quark magneton $\mu_{\mathrm{u}}$, while that of $\Xi^{`}{ }_{\mathrm{cb}}{ }^{+}(\{\mathrm{cb}\} \mathrm{u})$ is equal to $\left(2 \mu_{\mathrm{c}}+2 \mu_{\mathrm{b}}-\mu_{\mathrm{u}}\right) / 3$. However baryons of this quark content in the model of Ono_1978 have large non-diagonal mass terms, so one should choose as the wave function of the baryon a linear combination of baryons $\bar{\Xi}_{\mathrm{cb}}{ }^{+}$and $\Xi^{`}{ }_{\mathrm{cb}}{ }^{+}$with the mixing angle $\alpha=68.13^{0}$ (cf. Table 1). Then for the magnetic moments we have:

$$
\begin{aligned}
& \left\langle\Xi_{c b}{ }^{+\alpha}\right| \mu\left|\Xi_{c b}+\alpha\right\rangle= \\
& =\left(2 \mu_{\mathrm{c}}+2 \mu_{\mathrm{b}}-\mu_{\mathrm{u}}\right) / 3 \sin ^{2} \alpha+\mu_{\mathrm{u}} \cos ^{2} \alpha-2 / \sqrt{ } 3 \sin \alpha \cos \alpha\left(\mu_{\mathrm{c}}-\mu_{\mathrm{b}}\right)= \\
& =\left(1-4 / 3 \sin ^{2} \alpha\right) \mu_{u}=-0.148 \mu_{\mathrm{u}} ;
\end{aligned}
$$

$$
\left\langle\Xi_{c b}{ }^{+a}\right| \mu\left|\Xi_{c b}{ }^{+a}\right\rangle=
$$

$$
=\left(2 \mu_{\mathrm{c}}+2 \mu_{\mathrm{b}}-\mu_{\mathrm{u}}\right) / 3 \cos ^{2} \alpha+\mu_{\mathrm{u}} \sin ^{2} \alpha+2 / \sqrt{ } 3 \sin \alpha \cos \alpha\left(\mu_{\mathrm{c}}-\mu_{\mathrm{b}}\right)=
$$

$$
=\left(-1 / 3+4 / 3 \sin ^{2} \alpha\right) \mu_{u}=0.815 \mu_{u} .
$$

where we have neglected $\mu_{\mathrm{c}}$ and $\mu_{\mathrm{b}}$ in comparison to $\mu_{\mathrm{u}}$.
These predictions do not depend on the particular choice of the baryon pair $\Xi_{c b}{ }^{+}$ and $\Xi_{c b}{ }^{+}$provided one takes the mixing angle $\alpha$ corresponding to the given combination, and differ considerably from the predictions given by the "pure" states $\Xi_{\mathrm{cb}}{ }^{+}(\{\mathrm{cb}\} \mathrm{u})$ and $\Xi^{\mathrm{cb}^{+}}{ }^{+}(\{\mathrm{cb}\} \mathrm{u})$ (cf. Table 2$)$.

Table 2. Magnetic moments of double-flavored baryons in NRQM for "pure" and mixed states (with index $\alpha$ )

| Baryon | NRQM | NRQMa |
| :---: | :---: | :---: |
| $\overline{\underline{C l b}}^{\text {( }}$ (cb] u$)$ | $\mu_{u}$ | $-0.148 \mu_{u}$ |

## Mixing of the states $\bar{\Xi}_{\mathrm{cb}}, \bar{\Xi}_{\mathrm{cb}}$ ' in QCD sum rules

The problem of the $\bar{\Xi}_{\mathrm{cb}}, \bar{\Xi}_{\mathrm{cb}}$ ' mixing can also be analyzed within the QCD sum rules framework. The main difference in this case is that, rather than working with the mass matrix, one deals with correlation functions of interpolating currents, i.e. the role of mass matrix elements is played by correlators \{SVZ_1978\}\{loffe_1981\}
$\Pi^{\equiv c b, ~ \equiv c b}{ }^{`}=i \int d^{4} x e^{i \mathrm{ipx}}<0\left|T\left\{\eta^{\equiv c b, \equiv c b}{ }^{`}(x), \eta^{\equiv c b, \equiv c b `}(0)\right\}\right| 0>$, which are calculated,
(1)in QCD, using OPE, and
(2) by inserting a complete set of physical states.

Performing Borel transformation to suppress high--excited states and equating both expansions one obtains QCD sum rules loffe_1981.

QCD\&Work 2010, International Workshop on Quantum Chromodynamics - Thery and Experiment In this case, mixing causes the non-diagonal correlation functions to have nonzero values.

Prior to performing calculations of the physical properties, such as the magnetic moments, meson couplings etc., of the baryons, one should make sure that the corresponding interpolating currents have zero non-diagonal correlators.

To find the combination of $\eta^{\equiv c b}$ and $\eta^{\equiv c b `}$ that have zero non-diagonal correlator, consider the following interpolating currents that are obtained from them after a rotation by $\alpha$ :
$\eta_{\alpha^{`}}=\eta^{\equiv c b}{ }^{\circ} \cos \alpha+\eta^{\equiv c b} \sin \alpha, \quad \eta_{\alpha}=-\eta^{\equiv c b}{ }^{`} \sin \alpha+\eta^{\equiv c b}{ }^{`} \cos \alpha$, where the mixing angle $\alpha$ should be chosen such that:
$\Pi_{\alpha} \equiv \mathrm{cb}, \equiv \mathrm{cb}{ }^{`}=\mathrm{i} \int \mathrm{d}^{4} \mathrm{x} \mathrm{e}^{\mathrm{ipx}}<0\left|\mathrm{~T}\left\{\eta_{\alpha}(\mathrm{x}), \eta_{\alpha}(0)\right\}\right| 0>=0$
goes to zero.
Let us study this problem on a simplified toy-model using the QCD mass sum rules Zhu_1997 written for the octet hyperons $\Sigma$ and $\wedge$. Generalization to our case seems not to be without problems but is sufficient for our purposes.

Omitting the vacuum expectation values of the quarks c and b and neglecting mass of the $u$ quark in the QCD sum rules, we construct following Zhu_1997 the QCD mass sum rule for the baryon $\bar{\Xi}_{c b}{ }^{\prime}(\{u b\} c)$

QCD\&Work 2010, International Workshop on Quantum Chromodynamics - Thery and Experiment $\Pi_{a}{ }^{\equiv c b}{ }^{`}\left(M^{2}\right)=\left(M^{6} / 8 L^{4 / 9}\right) E_{2}+\left(b M^{2} / 32 L^{4 / 9}\right)+\left(M^{2} / 4 L^{4 / 9}\right) a_{u} m_{b} E_{0}-\left(3 m_{0}^{2} / 48\right.$ $\left.L^{26 / 27}\right) a_{u} m_{b}=\beta \Xi^{2} e^{-(M \equiv 2 / M 2), ~}$
where $\mathrm{a}_{\mathrm{q}}, \mathrm{b}$ and $\mathrm{a}_{\mathrm{q}} \mathrm{m}_{0}{ }^{2}$ are defined as loffe_1981:
$a_{q}=-(2 \pi)^{2}<q q>, b=<g_{c} G^{2}>, L=\ln \left(M^{2} / \Lambda^{2}\right) / \ln \left(\mu^{2} / \Lambda^{2}\right)$,
$a_{q} m_{0}^{2}=(2 \pi)^{2}<g_{c} q(\sigma G) q>, q=u, d, s$,
$\mu$ being renormalization point, while $G$ is a gluon field
with the coupling $g_{c}$ to quarks.
The corresponding sum rule for the $\wedge$ - like baryon $\bar{\Xi}_{\mathrm{cb}}$ ([ub]c) reads:
$\left(M^{6} / 8 L^{4 / 9}\right) E_{2}+\left(b M^{2} / 32 L^{4 / 9}\right)+\left(M^{2} / 12 L^{4 / 9}\right) a_{u}\left(2 m_{c}-m_{b}\right) E_{0}-\left(3 m_{0}^{2} / 48 L^{26 / 27}\right) a_{u}$ $\left(2 m_{c}-4 m_{b}\right)=\beta \equiv^{2} e^{-(M \equiv 2 / M 2),}$

The non-diagonal correlation function after Borel transformation can also be written as:
$\Pi_{\alpha} \equiv c b \equiv c b{ }^{`}\left(M^{2}\right)=\left[\left(M^{2} / 6 L^{4 / 9}\right) E_{0}-m_{0}^{2} / 24 L^{26 / 27}\right] a_{u} m_{c}$

Requiring that $\Pi_{\alpha} \equiv \mathrm{cb}, \equiv \mathrm{cb}=0$ leads to the value of the mixing angle given by:
$\tan 2 \alpha_{(\mathrm{ub}) \mathrm{c}}=\sqrt{ } 3 \mathrm{~m}_{\mathrm{c}} /\left(2 \mathrm{~m}_{\mathrm{b}}-\mathrm{m}_{\mathrm{c}}\right) \sim 0.342$.

Finally for baryons $\bar{\Xi}_{\mathrm{cb}}{ }^{`}(\{\mathrm{cb}\} \mathrm{u})$ and $\overline{\mathrm{E}}_{\mathrm{cb}}([\mathrm{cb}] \mathrm{u})$ one obtains $\tan 2 \alpha_{(c b) u}=\sqrt{ } 3\left(m_{c}-m_{b}\right) /(m c+m b) \sim-0.872$.

These formulae are transformed from one into the other by shifting the angle a by $60^{\circ}$ and $120^{\circ}$.

At $m_{c}=1650 \mathrm{MeV}, \mathrm{m}_{\mathrm{b}}=5 \mathrm{GeV}$ one obtains
$\alpha_{(\mathrm{ub}) \mathrm{c}} \sim 9.5^{0}, \quad \alpha_{(\mathrm{cb}) \mathrm{u}} \sim 69.5^{\circ}, \quad \alpha_{(\mathrm{uc}) \mathrm{b}} \sim 129.5^{0}$.
It is of interest to note that mass relations of QCD in this approximation yield somewhat unexpected result that the minimal mixing angle favors the diquark pair (ub) while others lead to large mixing angles.

Calculation of the magnetic moments of the double-flavored baryons in the quark model with the mixing angles from the QCD toy-model yield practically the same results as the quark model of Ono_1978.

## Conclusion

We have tried to show the importance of mixing
of heavy cascade baryons $\bar{\Xi}_{\mathrm{cb}}, \bar{\Xi}_{\mathrm{cb}}{ }^{`}$ in analysis of their characteristics.
As an example, the non-relativistic quark model of Ono_1978 is used.
The same approach is applied to the interpolating currents of these baryons in the framework of the QCD sum rules which is shown on the example of simplified mass QCD sum rules. The main conclusion is that in any given model of heavy baryons, one should first find the quark configuration leading to vanishing diagonal matrix elements. After finding the physical states, one should perform calculations of the various characteristics of these baryons. In the case of the QCD sum rules where there is no mass formulae in the common sense of the word, the problem of the truthful combination of interpolating currents deserves further study.
