Statistical fluctuations of radiation in quasi-Cherenkov generators

Tuesday, 27 September 2016 18:40 (0 minutes)

Shot noise, intrinsic to electron beams, is the cause of statistical fluctuations in radiation generated by quasi-Cherenkov generators operating in stationary and non-stationary regimes. Radiated power and instability time growth are the main output parameters characterizing the dynamics of electron beam interacting via the radiation field. Shot-noise related fluctuations of radiated power and instability time growth impose appreciable limitations on the possibility of coherent summation of electromagnetic oscillations from several quasi-Cherenkov generators operating in microwave and terahertz ranges [1,2]. The optimal conditions minimizing the spread of the main output parameters have been found for stationary and non-stationary regimes of quasi-Cherenkov generator operation.
