Reaction production + AMS: An alternative method to study $(d,\alpha)^{26}\text{Al}$ and $(p,\gamma)^{26}\text{Al}$ reactions at low energies

Thursday, 22 June 2017 15:00 (30 minutes)

It is well known the importance in Astrophysics of the reactions regarding ^{26}Al . This radioisotope is presented for instance, in the stars where there is H, C and Ne fusion at high temperatures; as well it can be found inside meteorites where it can be deposited or to be created in situ [1]. Considering the importance of the ^{26}Al nuclei, in this work are presented the first results regarding a campaign of measurements related with this radioisotope production, taking advantage of two different facilities: first, the radionuclide is produced by means of irradiation of silicon and magnesium targets with light particles, in order to produce (d,α) and (p,γ) reactions at low energies by using a CN-Van der Graaff accelerator. Once the enrichment with ^{26}Al was made, the targets are analyzed in an AMS machine with the aim to obtain the $^{26}\text{Al}/^{27}\text{Al}$ ratios [2]. These values can later be used to approach the cross section of ^{26}Al directly related with the reaction used for its production. With this alternative method, it is possible to measure very acceptable small cross sections of low energy reactions, due to the typical high resolution of AMS technique. In this work are presented our preliminary results for the $^{28}\text{Si}(d,\alpha)^{26}\text{Al}$ reaction cross sections around 1.5 MeV [3] as well as the first approximations for the $^{25}\text{Mg}(p,\gamma)^{26}\text{Al}$ reaction cross sections below 1 MeV.
