**A Quantitative variable** is numerical and represents a measurable quantity (continuous or discrete)

Family                      Size

**A Categorical variable** takes on values that are names or labels

Hair colors                      Sex

**DATA is a table with**

- **p columns** : realizations of the random variables
- **n rows** : observations of the statistical unit

**Apply methods**  
Choice of the method depends on

- The nature of the variables
- The size of the data
- The objective

# Basic data mining objective

## Supervised learning / Prediction

Explain a target variable with other variables

- Quantitative target

### Regression

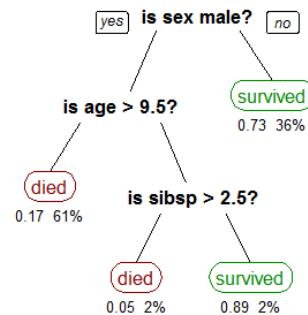

- ✓ linear regression
- ✓ SVR
- ✓ neural network
- ✓ ...

- Categorical target

### Classification

- ✓ logistic regression
- ✓ decision tree
- ✓ neural network
- ✓ ...

## Unsupervised learning / Description

Describe hidden structure from unlabeled data

- Description

Summarize the variables, detect link between Variables, detect outliers, ...

- ✓ Graphical and numerical description
- ✓ PCA, CA, ...
- ✓ ...

- Clustering

Organizing objects into groups (clusters) such that the members in each Group are similar

- ✓ K-means
- ✓ Hierarchical clustering
- ✓ ...

# Overfitting and generalization

The goal of supervised learning is to find a model  $f$  such as  $Y=f(X_1, \dots, X_p)+\epsilon$ , where  $\epsilon$  is an error

## Error measurement

- Regression : sum of residuals

$$\sum_{i=1}^n L(y_i - f(x_i))$$

where  $L$  is a cost function (e.g.  $L(u)=|u|$ ,  $L(u)=u^2$ )

- Classification : confusion matrix

		Predicted cluster			
		C1	C2	...	Ck
True cluster	C1				
	C2				
	...				
	Ck				

diagonal  
=  
good prediction

*underfitting*

*good fitting*

*overfitting*

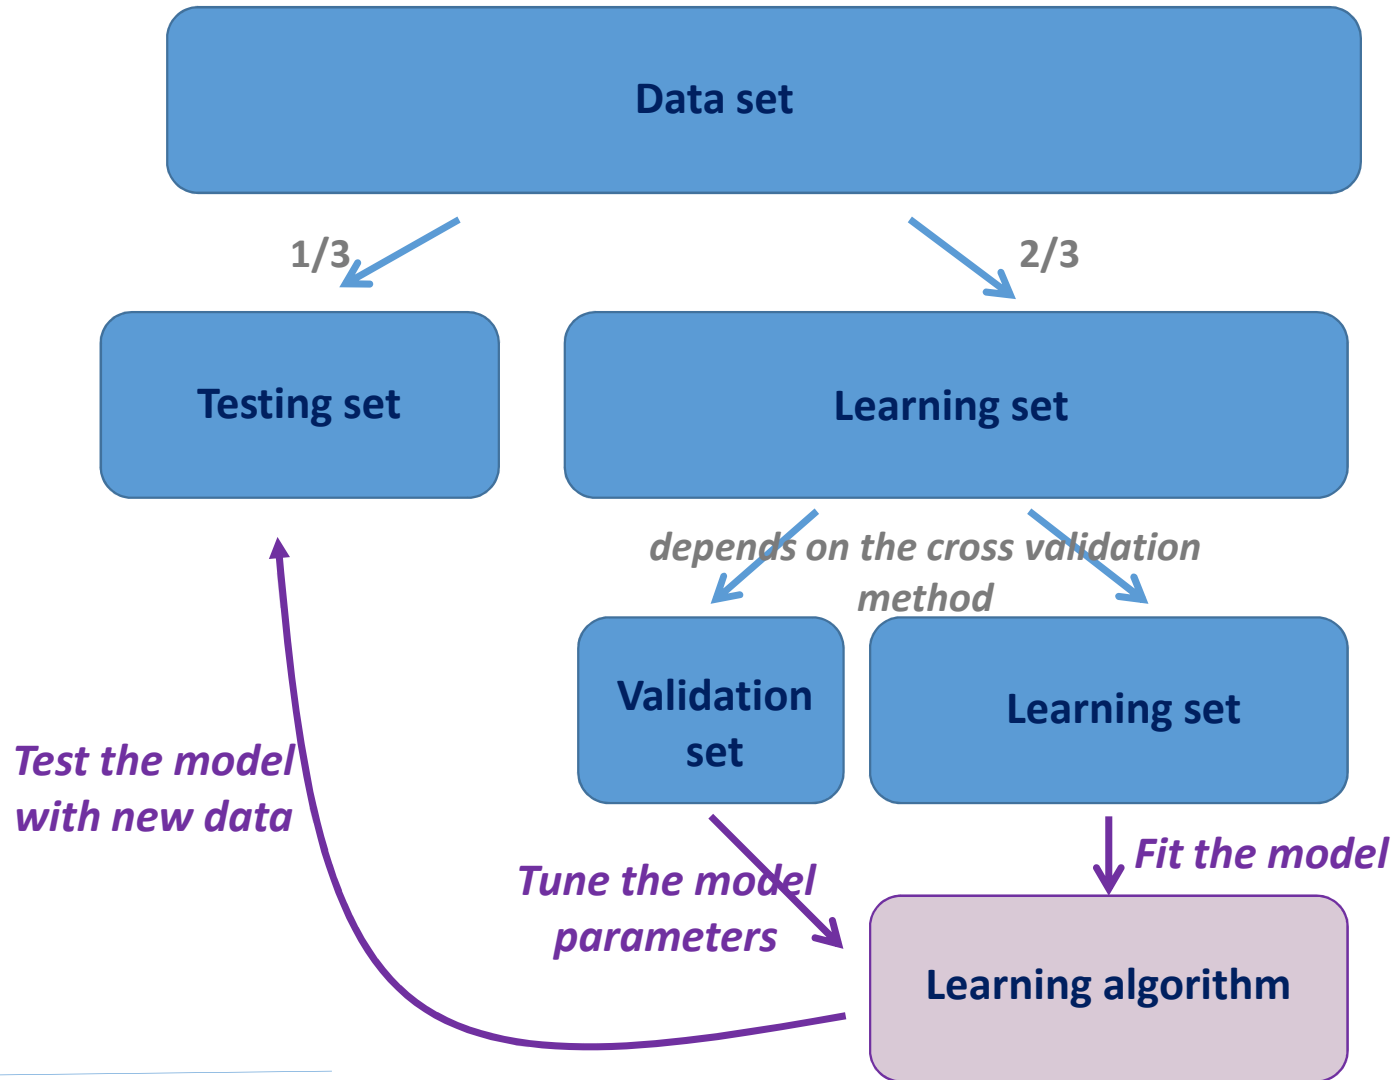

## Two kinds of errors :

- **Fitting error** : computed on the training dataset . A small error means that the model reproduced the training dataset well
- **Prediction error** : computed on a new dataset. A small error means that the model is able to predict new values

# The curse of dimensionality

Dimension = number of variables

When the dimensionality increases, the volume of the space increases so fast that the available data become sparse.

*The universe is full of empty space*

- Impossible to analyse and organize sparse data
- An enormous amount of training data are required to ensure a good exploration of a high dimensional space.

d	Covering		
	Vol. hypercube	Vol. sphere	%
2	4	3,1	78,5%
4	16	4,9	30,8%
6	64	5,2	8,1%
8	256	4,1	1,6%
10	1024	2,6	0,2%

Grid with 2 levels =  $2^d$  points (e.g.  $d=20 \Rightarrow 33554432$  points)  
 $k$  levels =  $k^d$  points (e.g.  $k=5$  and  $d=10 \Rightarrow 9765625$  points)

## Dimensionality reduction

# Dimensionality reduction

A large number of variables (features):

- increases overfitting
- contains redundant variables
- increases the training time and requires a large amount of memory and computation power

## Feature selection

*Selection of a subset of relevant features for a model*

Feature selection algorithms remove :

- ✓ redundant variables (correlated, mutual information,...)
- ✓ irrelevant variables (measure of accuracy, AIC, BIC, MSE...) (**risk of overfitting**)

## Feature extraction

*Creation of new variables from the original variables*

- ✓ Linear (e.g. PCA) or nonlinear transformation (e.g. kernel PCA)
- ✓ Criteria to measure the « loss of information » (variance, pairwise distances ,...)

# Principal component analysis (PCA)

p-dimensional coordinate system defined by the variables

Transformation of the original coordinate system to an orthogonal coordinate system

p-dimensional coordinate system defined by the principal axis

Figure 1.P. Fenelon

Dimensionality reduction  
 =  
 Projection on vect $\{u_1, \dots, u_k\}$   
 where  $k \ll p$   
 $\Rightarrow$   
 loss of information

# Principal component analysis

## Information

The information is the inertia of the data set

$$I = \frac{1}{n} \sum_{i=1}^n \|e_i - g\|^2$$

where  $g$  is the gravity center of the data (mean). Note that  $I = \text{tr}(V)$  where  $V$  is the covariance matrix (Inertia = sum of variances).

	Pop. (T)	Life exp.	Nb. child
Argentina	41050	75,87	2,19
Armenia	3099	74,44	1,77
...			

Distance between Argentina and Armenia  
 $= (41050-3099)^2 + (75,87-74,44)^2 + (2,19-1,77)^2 = 1440278405$   
 $\cong (41050-3099)^2$

Reduced and centered variables :

$$X_i^k \leftarrow \frac{X_i^k - \bar{X}^k}{S_k}$$

## Orthogonal random variables

Scalar prod. :  $\langle X^k, X^h \rangle = E[X^k X^h]$

$\langle X^k, X^h \rangle = \text{cov}(X^k, X^h)$

Centered variables

Norm :  $\|X\|^2 = E[X^2]$

$\|X\|^2 = \text{var}(X)$

$\cos(\hat{X}^k, \hat{X}^h) = \frac{\langle X^k, X^h \rangle}{\|X^k\| \|X^h\|}$   
 Cosine between two variables  
 Linear correlation coef.

$$r(X^k, X^h) = \frac{\text{cov}(X^k, X^h)}{\sqrt{\text{var}(X^k) \text{var}(X^h)}}$$

**Orthogonal variables**  
 =  
**uncorrelated variables**

# Principal component analyse

## Construction of the principal axes

- The 1<sup>st</sup> principal axis ( $u_1$ ) catches a maximum variance (inertia).
- The 2<sup>nd</sup> principal axis ( $u_2$ ) catches the maximum of the remaining variance and is orthogonal to the 1<sup>st</sup> axis
- Each succeeding component is built in the same way until the last axis ( $u_p$ )

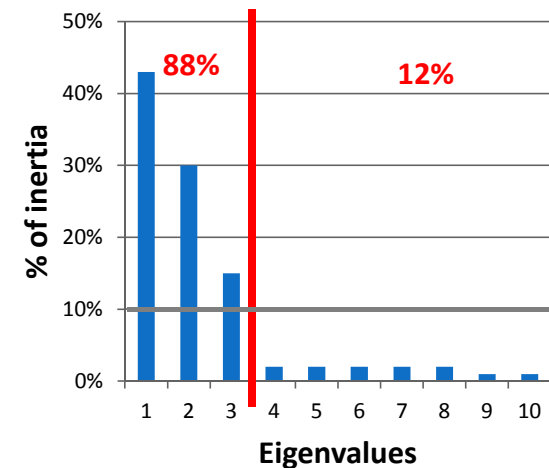

## Solution

The principal axes are the eigenvectors associated to the eigenvalues  $\lambda_1, \dots, \lambda_p$  of the covariance matrix  $V$  such that  $\lambda_1 > \dots > \lambda_p$ .

- Inertia of the data projected on  $u_k$  is  $\lambda_k$
- Inertia of the data projected on  $\langle u_1, \dots, u_k \rangle$  is  $\lambda_1 + \dots + \lambda_k$
- Total inertia is  $I = \lambda_1 + \dots + \lambda_p$

The principal components are the components of the data projected on the principal axis.

**!!! PCA is sensitive to outliers !!!**
