

A discussion on the 750 GeV diphoton anomaly

Marco Nardecchia

DAMTP and Cavendish Laboratory,
University of Cambridge

Wednesday 6 April 2016, LNF

Outline

- BSM at the beginning of Run 2
- Diphoton anomaly phenomenological aspects
- Weakly coupled extensions
- Strongly coupled extensions
- Conclusions

New Physics

- SM is very successful in describing physics up to the EW scale
- SM is not a complete theory (neutrino masses, dark matter, baryon asymmetry)

$$\mathcal{L}_{\text{eff}} = \mathcal{L}_{\text{SM}} + \sum \frac{c_i^{(d)}}{\Lambda^{(d-4)}} O_i^{(d)} (\text{SM fields}).$$

- Big question is $\Lambda?$
- Unfortunately, no unique indication from **observed** BSM physics
 1. Neutrino masses, from Dirac neutrino to GUT see-saw
 2. Dark Matter, from axions to Wimpzillas
 3. Baryon asymmetry, from EW baryogenesis to GUT baryogenesis
- However we have a **theoretical** guideline....

New Physics

- Upper bound from naturalness of the Higgs mass

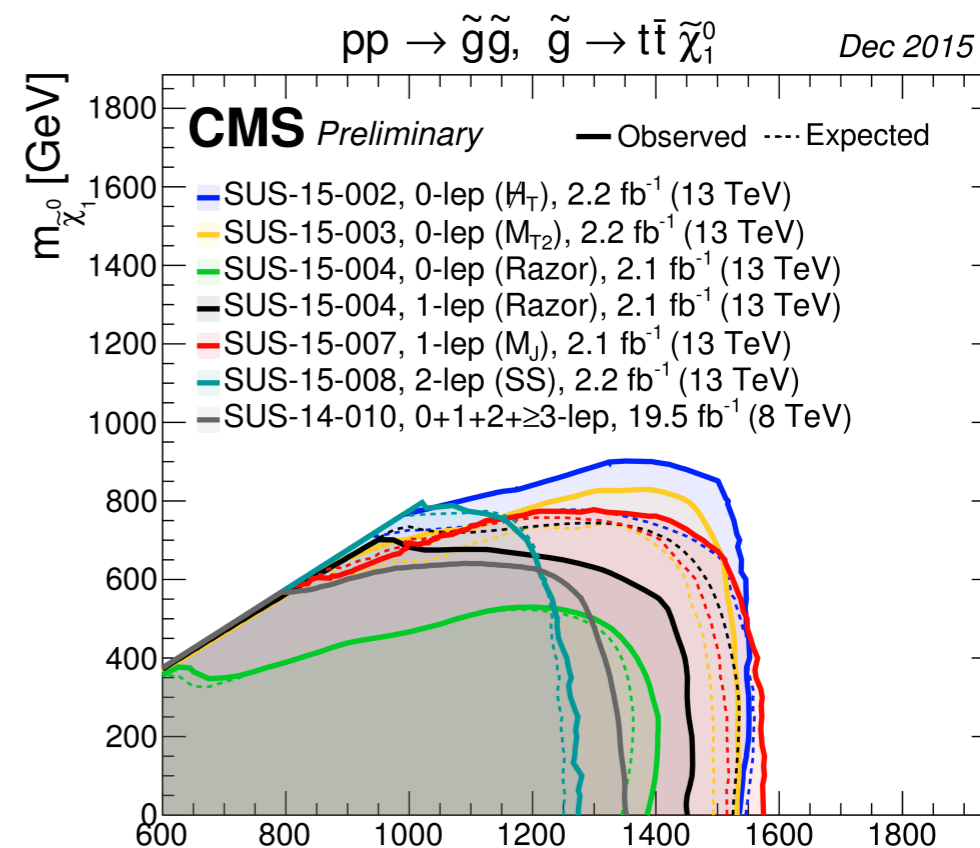

$$\Lambda < 1 \text{ TeV}$$

$$m_H^2 = m_{\text{tree}}^2 + \delta m_H^2$$

$$\delta m_H^2 = \frac{3}{\sqrt{2}\pi^2} G_F m_t^2 \Lambda^2 \approx (0.3 \Lambda)^2$$

- Main frameworks to solve this problem: composite Higgs and Supersymmetry
- Prediction: new **colored** states (the lighter the better)
- Instead....

Flavour Anomalies

Z. Ligeti,
Moriond QCD 2016

Diphoton anomaly

[ATLAS-CONF-2015-081]

Bin[GeV]	650	690	730	770	810	850
N_{events}	10	10	14	9	5	2
$N_{\text{background}}$	11.0	8.2	6.3	5.0	3.9	3.1

[1512.05777]

[CMS-EXO-15-004]

EBEB
Barrel-Barrel

EBEE
Barrel-Endcaps

Bin[GeV]	700	720	740	760	780	800
N_{events} (EBEB)	3	3	4	5	1	1
$N_{\text{background}}$ (EBEB)	2.7	2.5	2.1	1.9	1.6	1.5
N_{events} (EBEE)	16	4	1	6	2	3
$N_{\text{background}}$ (EBEE)	5.2	4.6	4.0	3.5	3.1	2.8

[1512.05777]

- ATLAS: local significance of 3.9σ
- ATLAS: best fit is obtained for $\alpha = \Gamma/M = 6\%$
- CMS: local significance of 2.6σ (narrow width)

After Moriond EW 2016

- ATLAS: spin 2 analysis + re-analysis of Run 1
- CMS: improved detector calibration + analyzed dataset recorded a 0T

- Local significance: **2.9 σ**
- Combining with Run 1 data: **3.4 σ**
- Preference for a narrow width

Warning

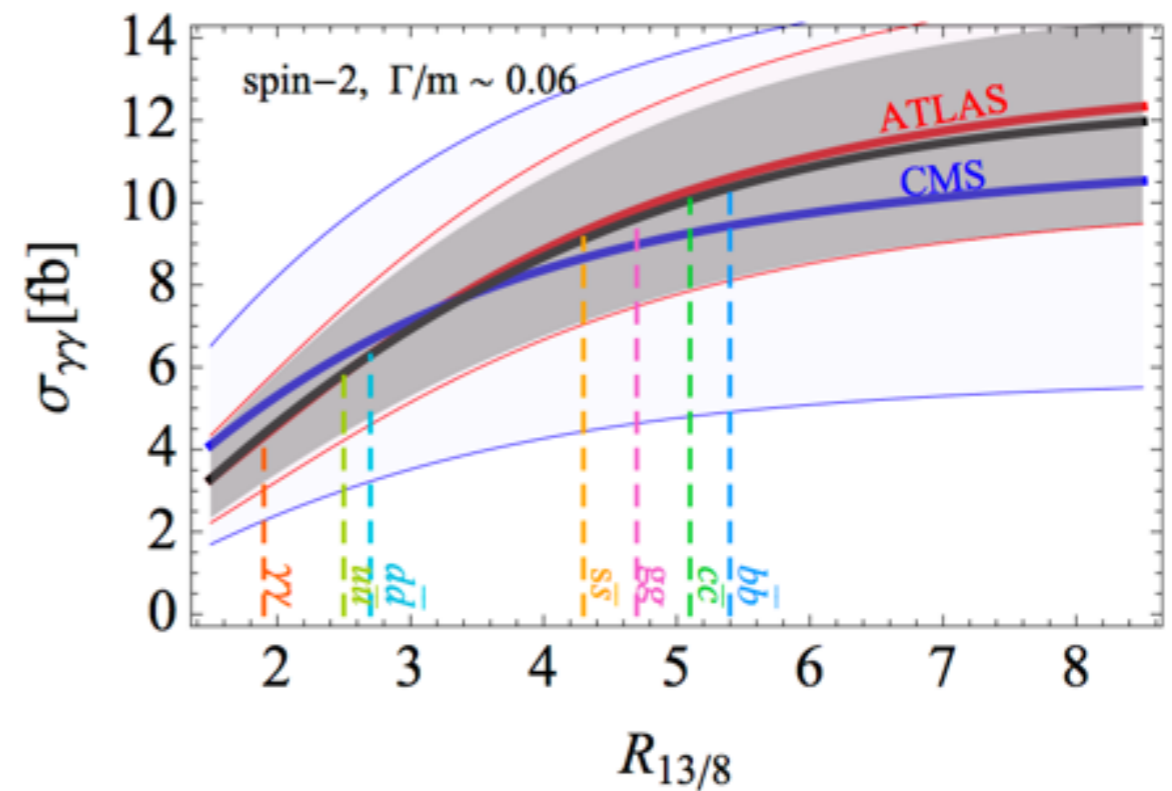

- **We need more data**, most likely just a statistical fluctuation
- However... more than **250** pre-prints on the arXiv
- I will try to give a (biased, partial and simplified) summary on possible interpretations of the anomaly in terms of New Physics, my **apologies** for the missing references/works/ideas
- I will consider only the simplest topology, interesting options have been discussed

- Focus on the s-channel 2 body decay, spin 0 or 2

Combinations

[1603.06566]

- Typical cross section: 1-10 fb

Consistency with LHC 8 TeV

[1512.04933

$$\sigma(pp \rightarrow \gamma\gamma) \approx \begin{cases} (0.5 \pm 0.6) \text{ fb} & \text{CMS [2]} & \sqrt{s} = 8 \text{ TeV}, \\ (0.4 \pm 0.8) \text{ fb} & \text{ATLAS [3]} & \sqrt{s} = 8 \text{ TeV}, \\ (6 \pm 3) \text{ fb} & \text{CMS [1]} & \sqrt{s} = 13 \text{ TeV}, \\ (10 \pm 3) \text{ fb} & \text{ATLAS [1]} & \sqrt{s} = 13 \text{ TeV}. \end{cases}$$

.....
.....
.....
.....
.....
.....
.....
.....

- An enhancement of the cross section is required $r \equiv \sigma_{13 \text{ TeV}} / \sigma_{8 \text{ TeV}}$
- Consistency (at 2σ) with LHC8 requires $r > 3.5$
- Cross section is given by $\sigma(pp \rightarrow S \rightarrow \gamma\gamma) = \frac{2J+1}{M\Gamma_S} \left[\sum_{\wp} C_{\wp\bar{\wp}} \Gamma(S \rightarrow \wp\bar{\wp}) \right] \Gamma(S \rightarrow \gamma\gamma)$
- Gain factor depends only on the type of p.d.f responsible for the production

$r_{b\bar{b}}$	$r_{c\bar{c}}$	$r_{s\bar{s}}$	$r_{d\bar{d}}$	$r_{u\bar{u}}$	r_{gg}	$r_{\gamma\gamma}$
5.4	5.1	4.3	2.7	2.5	4.7	1.9
✓	✓	✓	✗	✗	✓	✗

- Focus on two cases: gluon-gluon and bottom-bottom production
- Another option: change topology and kinematics \longrightarrow

[see, 1512.04928, 1512.06083, 1512.06113, 1512.06833, ..., ..., ...]

Production mechanism

$$\frac{\Gamma_{\gamma\gamma}}{M} \frac{\Gamma_{gg}}{M} \approx 1.1 \times 10^{-6} \frac{\Gamma}{M} \approx 6 \times 10^{-8}$$

$$\frac{\Gamma_{\gamma\gamma}}{M} \frac{\Gamma_{b\bar{b}}}{M} \approx 1.9 \times 10^{-4} \frac{\Gamma}{M} \approx 1.1 \times 10^{-5}$$

[1512.04933

....
....
....]

- Large partial width in diphoton

$$\Gamma_{\gamma\gamma}/M \gtrsim 10^{-6} \text{ narrow width}$$

$$\Gamma_{\gamma\gamma}/M \gtrsim 10^{-4} \text{ large width}$$

- In the gluon-gluon case, total width (if large) is dominated by decays into other channels

Decays into EW gauge bosons

[A discussion with David Marzocca (ETH)]

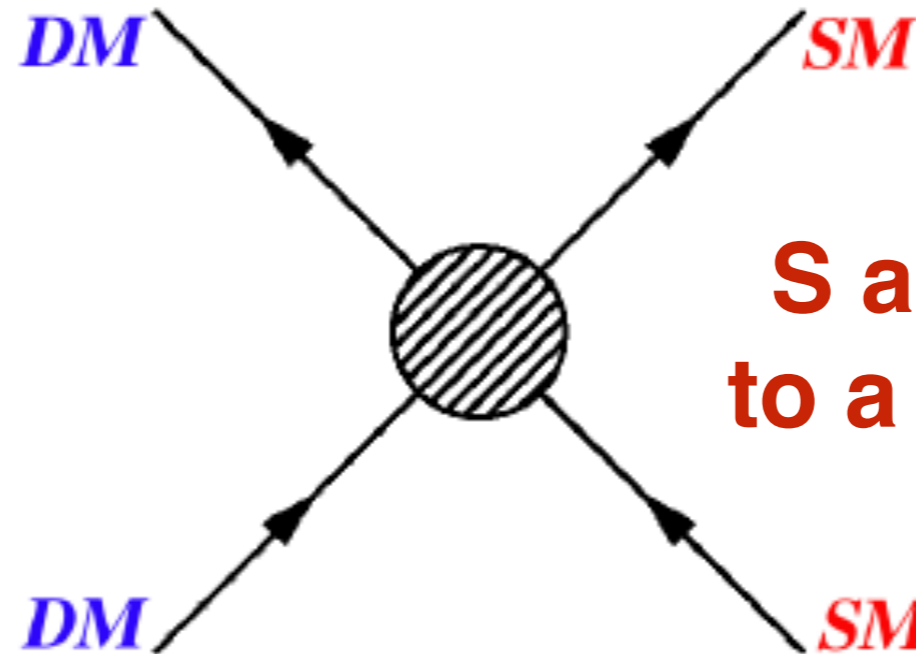

- In general we expect to see other decays at the LHC
- There is an evil region where Br are all small, more quantitative studies are needed to compare with the LHC

A Dark Matter connection

thermal freeze-out (early Univ.)
indirect detection (now)

direct detection

**S as mediator
to a dark sector**

production at colliders

Extra $\mathcal{Q} = \text{Dark Matter?}$

- 1) The connection with Ω_{DM} is interesting on its own;
- 2) if $\Gamma/M \sim 0.06$ allows to hide many particles that enhance $S \rightarrow \gamma\gamma$;
- 3) if $\Gamma/M \sim 0.06$ allows to get tree level $S \rightarrow \text{DM DM}$ decays.

Direct detection bounds are (weak) irrelevant if S is a scalar (pseudo-scalar).

Weakly coupled models

- Let's focus on the gg production mechanism, a simple renormalizable picture is given by SM extensions with vector-like fermions

- A simple toy model

Goertz, Kamenik, Katz, MN 1512.08500
same mechanism in O(100) papers

$$\begin{aligned}
 S &\sim (1, 1, 0) \\
 Q &\sim (\mathbf{3}, 1, 0) \quad \times N_Q \\
 E &\sim (1, 1, Y) \quad \times N_E
 \end{aligned}$$

$$\mathcal{L} \supset i y_q S \bar{Q} \gamma^5 Q + i y_e S \bar{E} \gamma^5 E$$

- A large diphoton rate is required

$$\Gamma(S \rightarrow \gamma\gamma) = M \frac{\alpha^2}{16\pi^3} Y^4 N_E^2 y_e^2 \tau_E |\mathcal{P}(\tau_E)|^2 \xrightarrow{M_E \rightarrow 400 \text{ GeV}} \frac{\Gamma(S \rightarrow \gamma\gamma)}{M} = 1.1 \cdot 10^{-7} Y^4 y_e^2 N_E^2$$

$\tau_E = 4M_E^2/M^2$

- Narrow** Width $\Gamma_{\gamma\gamma}/M \gtrsim 10^{-6} \longrightarrow Y^4 y_e^2 N_e^2 \gtrsim 10$

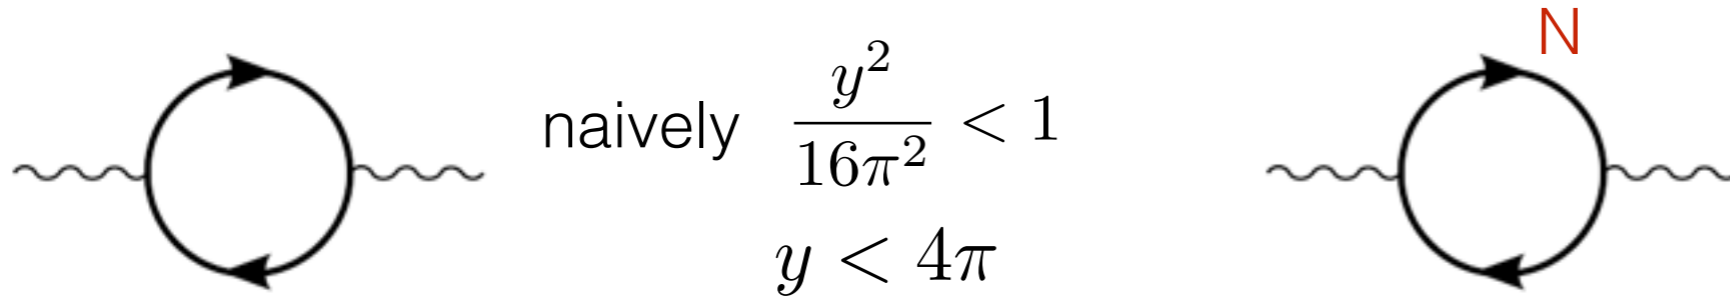

$Y^4 y_e^2 N_e^2 \approx 1.5$
for a top-like state

- Large** Width $\Gamma_{\gamma\gamma}/M \gtrsim 10^{-4} \longrightarrow Y^4 y_e^2 N_e^2 \gtrsim 10^3$

Calculability in perturbative models

- How large can the couplings and/or the number of states be?

naively $\frac{y^2}{16\pi^2} < 1$
 $y < 4\pi$

less naively $\frac{Ny^2}{16\pi^2} < 1$
 $y < 4\pi/\sqrt{N}$

- Other possible issues

1) Landau pole can be very close to the TeV scale

2) Beta function changes very rapidly compared with the coupling itself

$$\mu \frac{d}{d\mu} y = \beta_y \quad \mathcal{A} = y + \beta_y \log \left(\frac{\mu}{E} \right)$$

Possible criterion $\left| \frac{\beta_y}{y} \right| < 1$

 1512.07889,
 1512.08500,
 1602.01460,
,
,
,]

3) Vacuum stability, new interactions (and new scalars) can modify the scalar potential

4) Unitary implications from $2 \rightarrow 2$ scatterings of mediators

[with L. Di Luzio and J. Kamenik, tomorrow?]

- Strong constraints, a large width makes the interpretation of this anomaly in terms of weakly coupled models very challenging

The Usual Suspects

1512.05332

...

- Most economical attempt at the renormalizable level: **2 Higgs Doublet Model**

- Production: directly through quarks at the tree level
- Decay into photons: through **loops of SM particles**
- **TREE** level decays are available, for example

$$\frac{\Gamma_{\gamma\gamma}}{\Gamma_{t\bar{t}}} \simeq \frac{2\alpha^2 m_t^2}{27\pi^2 M^2} [\pi^2 + 4 \log^2(M/m_t)]^2 \simeq 10^{-5} \quad \times$$

- Requires other mediators in the loop as in the previous case (but now with more constraints: Higgs, EWPT, flavour, ...)

- **MSSM**: is a special 2HDM + other states (in particular stops and higgsinos)

- Enhancement for **extreme** values of the parameters (large A -terms, low values for soft masses) within the order of magnitude required to fit the diphoton data

- **RPV-MSSM** has problems too... 1512.07645

- **SUSY is not the MSSM**, extensions can reproduce the effect

Candidates in strongly coupled models

Composite neutral bosons of QCD

Strongly coupled models

- The 750 GeV state is a composite state of a strongly coupled sector
- Simplest idea: vector-like confinement (not direct connection with the EW breaking)

	$G_H = SU(N)$	$SU(3)_C$	$SU(2)_L$	$U(1)_Y$
Ψ_D	\square	$\bar{\square}$	$\mathbf{1}$	$1/3$
Ψ_L	\square	$\mathbf{1}$	\square	$-1/2$
$\bar{\Psi}_D$	$\bar{\square}$	\square	$\mathbf{1}$	$-1/3$
$\bar{\Psi}_L$	$\bar{\square}$	$\mathbf{1}$	\square	$1/2$

[From 1602.01092,
see also
1512.04850,
1512.04933
1602.07297
]

- $SU(N)$ gauge dynamics similar to QCD
- S is a pseudo-Goldstone boson associated to the breaking of the global symmetry

$$SU(5)_L \times SU(5)_R \rightarrow SU(5)_V$$

- Extra colored and charged “pions” are predicted

$$\pi \sim (\mathbf{8}, \mathbf{1}, 0) \oplus (\mathbf{3}, \mathbf{2}, -5/6) \oplus (\bar{\mathbf{3}}, \mathbf{2}, +5/6) \oplus (\mathbf{1}, \mathbf{3}, 0) \oplus \oplus (\mathbf{1}, \mathbf{1}, 0)$$

- Di-gluon and Di-photon couplings are generated by WZW terms

$$\frac{Ng_3^2}{32\sqrt{15}\pi^2 f} \phi \epsilon^{\mu\nu\rho\sigma} G_{\mu\nu}^a G_{\rho\sigma}^a - \frac{3Ng_2^2}{64\sqrt{15}\pi^2 f} \phi \epsilon^{\mu\nu\rho\sigma} W_{\mu\nu}^\alpha W_{\rho\sigma}^\alpha - \frac{Ng_1^2}{64\sqrt{15}\pi^2 f} \phi \epsilon^{\mu\nu\rho\sigma} B_{\mu\nu} B_{\rho\sigma}$$

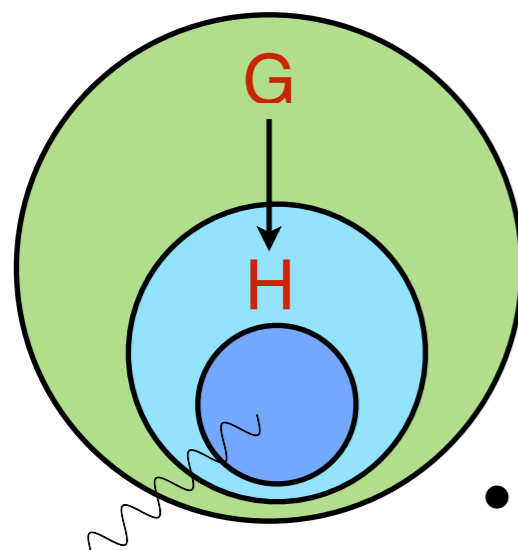

- Same as in QCD $\pi^0 \rightarrow \gamma\gamma$

Strongly coupled models

- Other phenomenological aspects of this class of theories:
 - 1) Large coset space contains **coloured pseudo-goldstone**
 - 2) $f \gtrsim v$, other strongly coupled resonances accessible at the LHC
 - 3) These models are automatically **MFV** (Minimally Flavour Violating) because of the gauge symmetry
 - 4) Other options can be explored (for example S is associated with an anomalous current like the eta' in QCD) [\[in particular see 1602.07297\]](#)
 - 5) Possible dark matter candidate(s) because of extra symmetries
- The bad side: there is no **direct** link with the EW symmetry breaking. More ambitious idea: Composite Higgs and S from the same strong dynamics

Eg:

$SU(2)_L \times U(1)_Y$

- In particular Higgs and S pseudo-NGB
- Non trivial G/H construction: UV realisation?
- Flavour through partial compositeness

$$\mathcal{L}_{\text{mix}} = \epsilon_L^i \bar{f}_L^i \Psi_R^i + \epsilon_R^i \bar{f}_R^i \Psi_L^i \Rightarrow y_{\text{SM}}^{ij} \sim \epsilon_L^i \epsilon_R^j g_*$$
- Large width $S \rightarrow \bar{t}t$

[\[1512.04929, 1512.04933, 1512.05330, 1512.07242, ...\]](#)

Spin 2

[1602.02793]

- A motivated candidate: KK graviton from a warped extra-dimension

$$\mathcal{L} \sim \frac{1}{M_{\text{Planck}}} T^{\mu\nu} h_{\mu\nu}^{(0)} + \frac{1}{M_{\text{Planck}} e^{-kb}} T^{\mu\nu} \sum h_{\mu\nu}^{(m)}$$

- Massless graviton is Planck suppressed, while the KK modes can have a TeV strength

- Couplings are universal, in particular $\Gamma(h_{\mu\nu}^{(1)} \rightarrow \gamma\gamma) = \frac{1}{8} \Gamma(h_{\mu\nu}^{(1)} \rightarrow gg)$

- Diphoton anomaly can be reproduced but now we have also another prediction

$$\Gamma(h_{\mu\nu}^{(1)} \rightarrow \gamma\gamma) = 2\Gamma(h_{\mu\nu}^{(1)} \rightarrow \ell^+ \ell^-)$$

- At the moment, absence of peaks in di-leptons in Run 2 data

$$\sigma(pp \rightarrow S \rightarrow \ell^+ \ell^-) < 5 \text{ fb} \quad [\text{ATLAS-CONF-2015-081}]$$

$$\sigma(pp \rightarrow S \rightarrow \ell^+ \ell^-) \lesssim 3 \text{ fb} \quad [\text{CMS-EXO-15-004}]$$

- Another candidate: a resonance from a strongly interacting theory, however difficult to motivate the absence of detection of states with lower spin

- Also, away from the energy-tensor limit, scatterings have very bad UV behaviour

Conclusions

- Experimental situation needs to be clarified, we need more data
- Information on the width is crucial for model building
- We expect to see more decays channels at the LHC, in particular decays into EW gauge bosons
- It is very plausible to have more states at or below the TeV
- Who ordered that? Which is the role of S in connection with other open issues of the SM? (**Naturalness problem** and origin of the EW scale, DM, flavour,)
