

CHARACTERISATION OF THE GET ELECTRONICS FOR SI DETECTOR APPLICATIONS

A.T. LAFFOLEY

ON BEHALF OF THE ACTAR TPC COLLABORATION

OUTLINE

- Overview of ACTAR TPC project
- Description of General Electronics for TPCs (GET)
- Overview of Si performance (baseline noise, resolution, etc.)
- Investigation of system dead time

WHAT IS AN ACTIVE TARGET?

- Based on time projection chamber (TPC) concept from particle physics
 - Gas is both detector **and** target
 - Event-by-event reconstruction in 3D
 - High efficiency (+ low energy threshold)
- Advantages over conventional approaches

- Thin target experiments:
 - Need very high rates
 - Not feasible with exotic nuclei
- Thick target experiments:
 - Significant losses in target
 - Degraded resolution

BASIC DESIGN ASPECTS

- **Drift Region**
 - Particles ionise gas along their trajectories
- **Amplification Region**
 - Micromegas – J. Pancin *et al.*, NIMA 735, 532 (2014)
- **Pixelated Pad Plane**
 - Very high density: $2 \times 2 \text{ mm}^2$ (= 25 channels/cm²)
 - Total 16384 fully digitised electronics channels (GET)
- **Auxiliary Detectors**
 - Telescopes for escaping particles (Si and/or CsI walls)
 - LaBr₃ or CeBr₃ for γ rays (SpecMAT, O. Poleshchuk)

ACTAR TPC: TIMELINE

- ERC Grant awarded to G.F. Grinyer for ACTAR TPC (Jan. 2014–Jan. 2019)
- 2012–2016: Research and Development
 - Building of prototype and tests
 - GET electronics development

ACTAR TPC ELECTRONICS

- Using GET (General Electronics for TPCs)
 - Wave digitiser using 512 analogue memory cells @ 100 MHz (max)
 - L0/L1/L2 trigger capabilities (external, multiplicity & higher order)
 - Zero suppression, full & partial readout for reducing data traffic
 - ANR funded project (Nov. 2009–Oct. 2013; IRFU/CEA, CENBG, GANIL, MSU)

Electronics exist and hardware is ready to use!

Courtesy of GET Collaboration

GET ARCHITECTURE

AGET

AGET:

- 64 input channels
- 4 fixed-pattern noise (FPN) channels
- 512 circular memory cells
- Four built-in preamplifiers with fixed gain (120 fC, 240 fC, 1 pC, 10 pC)
- Generates multiplicity signal

GET ARCHITECTURE

AsAd:

- 4 AGET/AsAd card
- 256 channels
- 12-bit ADC

GET ARCHITECTURE

CoBo:

- Up to 4 AsAd/CoBo
- 1024 channels
- Reads, reduces, and concentrates data

GET ARCHITECTURE

MuTanT:

- Distributes master clock
- Provides 3-level trigger system
(L0 = external, L1 = multiplicity, L2 = software level trigger)

μTCA Crate:

- Up to 11 CoBos (11264 channels)
- Adjustable writing clock frequency (1–100 MHz)
- Controlled by MuTanT

ACTAR TPC DEMONSTRATOR

- 2048-channel electronics test bench
 - Two detectors with identical chamber design (GANIL and CENBG)
 - Mechanics scalable to final design (1/8 scale)
 - 12 Si detectors perpendicular to beam axis
 - 4 DSSD downstream

Details

Channel DSSD

cm x 6.4 cm

Thickness: 1500 μm

4 detectors = 256 channels

DSSD CONNECTORS

N card = back strips

P card = front strips

Cable to AsAd

SAMTEC ERM8 ↔ ERM8

TRIGGER LOGIC

CoBo standalone (external trigger with internal multiplicity)

- L0 = external trigger (input)
- L1 = multiplicity trigger (output)
- L2 = CoBo busy signal (output)

L1 Trigger: $M = 1$ DSSD multiplicity

Triple α source for DSSD calibration

^{239}Pu (5.15 MeV); ^{241}Am (5.48 MeV); ^{244}Cm (5.8 MeV)

SAMPLE DSSD SIGNALS

DSSD Baseline Mean

DSSD Baseline σ

Detector biased to 150 V
(300 V full depletion)

Alpha Energies

Gain = 1 pC; Range = 17.5 MeV

Comparison between GET gain settings

Alpha Energies

DSSD SI RESOLUTION

Resolution @ 5.1 MeV

GET: 80 keV FWHM

Gain set to 1 pC

Energy range: 17.5 MeV

Baseline noise: 25–80 keV
(5–15 ADC channels)

RECOVERY OF SATURATED SIGNALS

Experiment @ IPNO:

^{12}C @ 6.6 MeV/u

He: $i\text{C}_4\text{H}_{10}$ (90%:10%) @ 1 atm

1 pC Gain = 17.5 MeV E_{range}

10 pC Gain = 175 MeV E_{range}

How to detect 20–30 MeV particles?

Saturated signal prevalence: 33% in DSSD, 7% in MAYA, 2% in Pads

RECOVERY OF SATURATED SIGNALS

Experiment @ IPNO:

^{12}C @ 6.6 MeV/u

He: $i\text{C}_4\text{H}_{10}$ (90%:10%) @ 1 atm

1 pC Gain = 17.5 MeV E_{range}

10 pC Gain = 175 MeV E_{range}

How to detect 20–30 MeV particles?

Saturated signal prevalence: 33% in DSSD, 7% in MAYA, 2% in Pads

TESTING MUTANT DEAD TIME

- **Trigger:** Poisson distributed random pulser
- **Dead time:** Measured per event from MuTanT LEMO output
- **Live time:** Measured accepted trigger requests as TVal LEMO output. Ratio of trigger requests to accepted triggers gives live time

MUTANT DEAD TIME

- MUTANT dead time signal width measured with oscilloscope

- Dead time set only by AGET chip with most channels being read (parallelisation at AGET level)

MUTANT DEAD TIME

- MUTANT dead time signal width measured with oscilloscope

- Dead time set only by AGET chip with most channels being read (parallelisation at AGET level)

$$P(R\tau) = 1 - e^{-R\tau}$$

where R is trigger request rate and τ is dead time per event

$$LT(R\tau) = 100e^{-R\tau}$$

System Live Time vs. Channels Read

Assuming a Mutant overhead of 52.5 μ s and 20.5 μ s to read each channel (all 512 time buckets read)

Dead time dominated by bursting associated with 800 Mbit/s data transfer rate limit

SYSTEM LIVE TIME

System Live Time vs. Channels Read

Assuming a Mutant overhead of 52.5 μ s and 20.5 μ s to read each channel (all 512 time buckets read)

SYSTEM LIVE TIME

System Live Time vs. Channels Read

Assuming a Mutant overhead of 52.5 μ s and 20.5 μ s to read each channel (all 512 time buckets read)

CONCLUSION AND SUMMARY

- DSSD Si resolution ~**80 keV** FWHM (@ 5.1 MeV) with GET
- Energy range:
 - 120 fC – 2.5 MeV
 - 240 fC – 5 MeV
 - **1 pC – 20 MeV**
 - 10 pC – 200 MeV
- Baseline noise: **25 keV** (~5 ADC channels)
- System live time can be estimated knowing:
 - Max channels read on a single AGET
 - Max channels read on a single CoBo
 - Trigger delay
 - Time buckets read per channel
 - Trigger request rate
