Cosmic Rays

A mysterious radiation

1903: Rutherford and others found that that the ionization was reduced when electroscopes were shielded of radioactivity.

- The belief spread that the penetrating radiation came from radioactive material in Earth's crust...!
- How should such radiation decrease with increasing height ...?

1909: Theodor Wulf could measure ion-production rates as low as one ion-pair/s. Took his electroscope to top of Eiffel Tower and found the rate much larger than expected.

1909-11: Swiss physicist **Albert Gockel** carried a Wulf-type electroscope on three balloon flights (4500m). He ascribed a considerable part of the ionization to gamma rays from 'radioactive substances in the atmosphere'.

Mysterious radiation from above

1910-14: Italian physicist **Domenico Pacini** made important but little noticed ionization measurements with an electroscope on land, at sea, and underwater. **He concluded that there was penetrating radiation in the atmosphere, independent of radioactive material in the crust...!**

1911-13: **Hess** designed Wulf-type electroscopes with 3 mm thick brass walls. He then made 10 balloon flights. **On 7 August 1912 the hydrogen filled balloon would carry him to an altitude of about 5000 m.**

This flight revealed a very significant increase of the ionization at high altitude. A month after the decisive flight he reported his results which became known as the discovery of galactic cosmic rays at a meeting in Munster.

V. F. Hess (1912). "Über Beobachtungen der durchdringenden Strahlung bei sieben Freiballonfahrten".

Physikalische Zeitschrift 13: 1084–1091

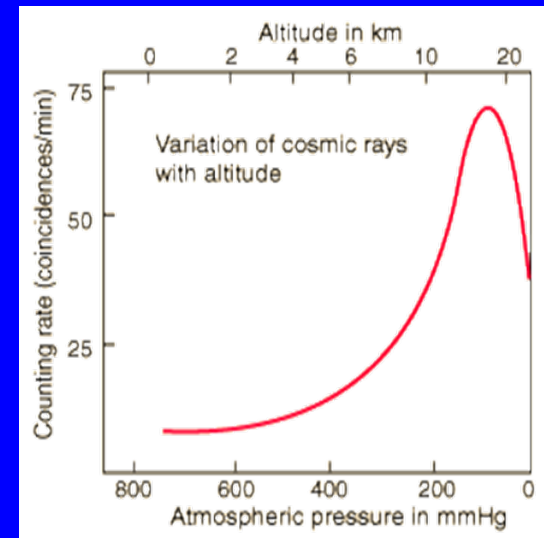

Mysterious space radiation

1914: Werner Kolhörster improved the Wulf electroscope, made five balloon flights in 1914. He reached 9300 m, measuring an ionization six times larger than at ground level, confirming Hess' result.

An unknown radiation from space with extreme penetrating power was causing the ionization.

No mentioning of cosmic rays or particles.

Some scientists were sceptical, especially Millikan in the USA. He could NOT confirm results with an unmanned balloon flight to 15 km over Texas.

Victor Hess

1883: Born in Austria...

1910: Earned his PhD at the University of Graz.

1912: August 7, conclusive 6 hour balloon flight to 4500m drifted 200 km north.

1925: Professor of Experimental Physics, University of Graz.

1931: Professor, and Director Institute of Radiology, University of Innsbruck.

1936: He was awarded Nobel Prize in Physics in 1936.

1938: Relocated to the USA. Fordham University appointed Professor of Physics.

1944: Became an American citizen.

1964: Died on December 17th.

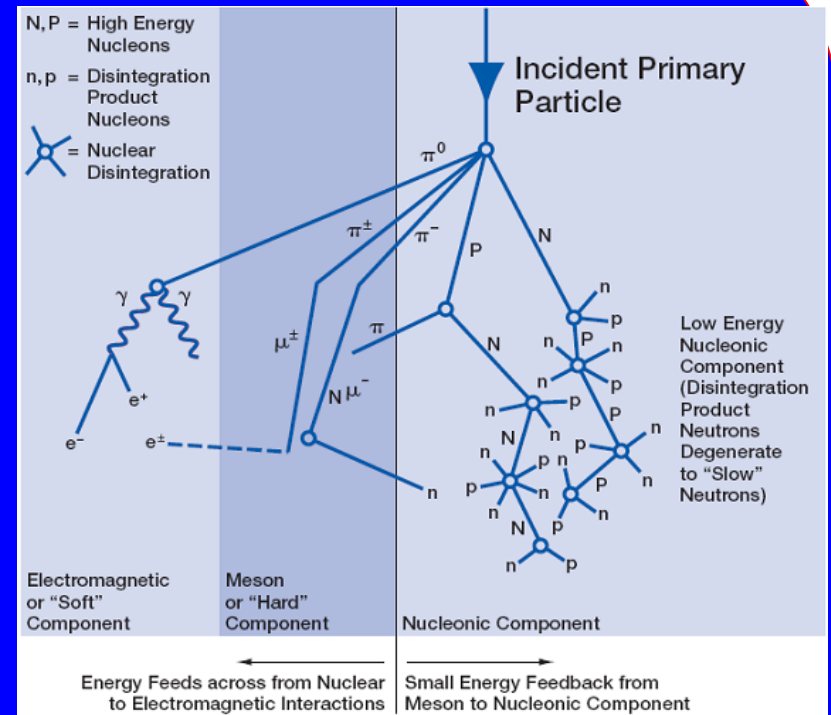

Cosmic rays as charged particles

1927: **Dmitri Skobeltsyn** in the Soviet Union had obtained a cloud-chamber photo that showed a cosmic-ray track...!

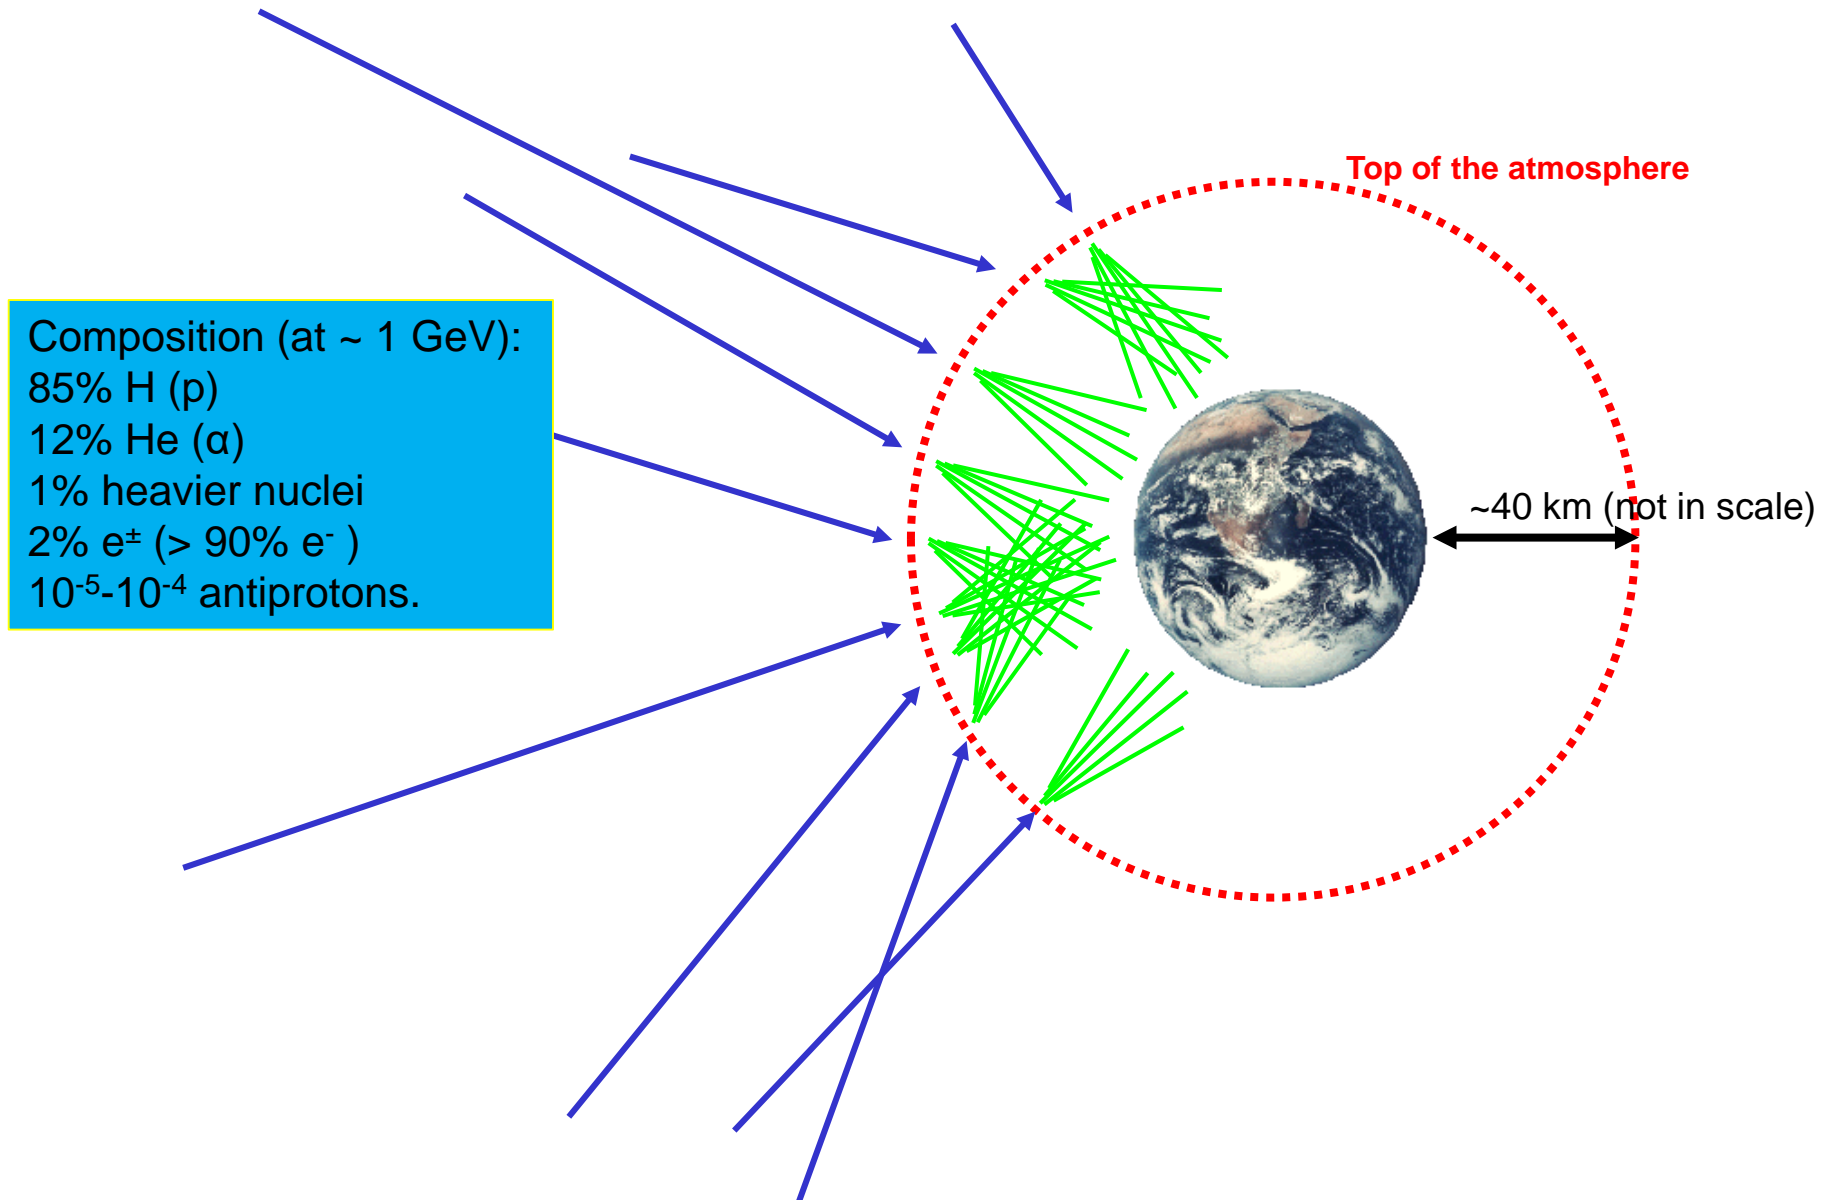

1932: **Bruno Rossi** found that the cosmic-ray flux contained a soft component and a hard component of charged particles with energies above 1 GeV...!

Then **Carl Anderson** (Caltech) discovered the positron. For this he shared the Nobel Price with Hess...!

1932-1953: Many new particles were discovered by studying cosmic ray showers... After two decades of such fundamental discoveries, 1953 marked the transition to accelerator-based particle physics.

A modern picture of the cosmic radiation

Antinuclei search	Sensitivity of $O(10^{-8})$ in He-bar/He	

- **Unprecedented statistics and new energy range** for cosmic ray physics
 - e.g. contemporary antiproton & positron energy, $E_{\text{max}} \approx 50 \text{ GeV}$
- Simultaneous measurements of many species
 - constrain secondary production models

Scientific goals

- Search for dark matter signals
- Search for antihelium (primordial antimatter)
- Study of cosmic-ray propagation (light nuclei and isotopes)
- Study of electron spectrum (local sources?)
- Study solar physics and solar modulation
- Study terrestrial magnetosphere

Scientific goals

- **Search for dark matter signals**
- Search for antihelium (primordial antimatter)
- Study of cosmic-ray propagation (light nuclei and isotopes)
- Study of electron spectrum (local sources?)
- Study solar physics and solar modulation
- Study terrestrial magnetosphere

The magnet

Characteristics:

- 5 modules of permanent magnet (Nd-B-Fe alloy) in aluminum mechanics
- Cavity dimensions (162 x 132 x 445) cm³
→ $GF \sim 21.5 \text{ cm}^2\text{sr}$
- Magnetic shields
- 5mm-step field-map on ground:
 - $B=0.43 \text{ T}$ (average along axis),
 - $B=0.48 \text{ T}$ (@center)

The tracking system

Main tasks:

- Rigidity measurement
- Sign of electric charge
- dE/dx (ionisation loss)

Characteristics:

- 6 planes double-sided (x&y view) microstrip Si sensors
- 36864 channels
- Dynamic range: 10 MIP

Performance:

- Spatial resolution: $\sim 3 \mu\text{m}$ (bending view)
- MDR $\sim 1 \text{ TV/c}$ (from test beam data)

The electromagnetic calorimeter

Main tasks:

- lepton/hadron discrimination
- $e^{+/-}$ energy measurement

Characteristics:

- 44 Si layers (x/y) + 22 W planes
- $16.3 X_0 / 0.6 \lambda_L$
- 4224 channels
- Dynamic range: 1400 mip
- Self-trigger mode (> 300 GeV; $GF \sim 600$ cm² sr)

Performance:

- p/e^+ selection efficiency $\sim 90\%$
- p rejection factor $\sim 10^5$
- e rejection factor $> 10^4$
- Energy resolution $\sim 5\%$ @ 200 GeV

The time-of-flight system

Main tasks:

- First-level trigger
- Albedo rejection
- dE/dx (ionisation losses)
- Time of flight particle identification ($<1\text{GeV}/c$)

Characteristics:

- 3 double-layer scintillator paddles
- x/y segmentation
- Total: 48 channels

Performance:

- $\sigma(\text{paddle}) \sim 110\text{ps}$
- $\sigma(\text{ToF}) \sim 330\text{ps}$ (for MIPs)

The anticounter shields

Main tasks:

- Rejection of events with particles interacting with the apparatus (off-line and second-level trigger)

Characteristics:

- Plastic scintillator paddles, 8mm thick
- 4 upper (CARD), 1 top (CAT), 4 side (CAS)

Performance:

- MIP efficiency > 99.9%

Neutron detector

Main tasks:

- e/h discrimination at high energy

Characteristics:

- **36 ^3He counters:**
 $^3\text{He}(n,p)\text{T}$ - $E_p=780$ keV
- 1cm thick polyethylene + Cd moderators
- n collected within 200 μs time-window

Main tasks:

- Neutron detector trigger

Characteristics:

- Plastic scintillator paddle, 1 cm thick

Shower-tail catcher

Satellite and space environment

- Large mechanical loads during launch phase
 - ⇒ random vibrations (all axis) 7.4 g rms, SRS (Shock Response Spectrum) -all axis- up to 400 g
- Low mass budget
- Thermal variations (5 - 40 °C in normal operations)
- Low power budget (⇒ small power consumption)
- Redundancy and safety (accurate design, no SPF)
- Protection against highly ionizing events (SEU and SEL)
- EMI/EMC issues
- Limited telemetry

PAMELA models

Mass/Thermal Model (MDTM):

- ⇒ Full cycle of vibration/shock
- ⇒ Thermal tests
- ⇒ Dimensional/transp. tests

Technological Model (TM):

- ⇒ Preliminary acceptance tests
- ⇒ Power on/off,telecommands
- ⇒ Data transmission to VRL
- ⇒ EMI/EMC tests

Flight Model (FM):

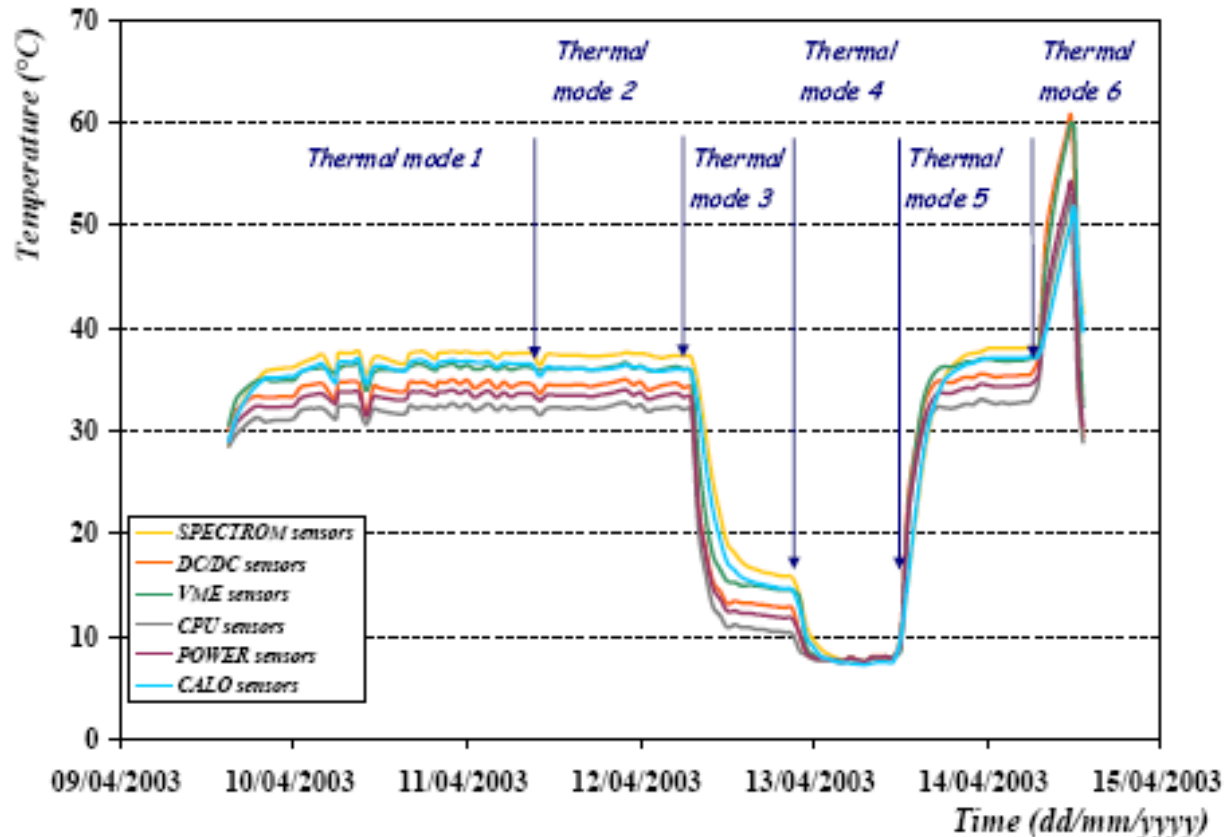

- ⇒ Beam tests;
- ⇒ Integration in the satellite
- ⇒ Pre-flight tests
- ⇒ Launch

Mechanical tests

The PAMELA MDTM during the vibration and shock tests at IABG mbH (Munich), August 2002

Thermal tests

Results of the PAMELA thermal qualification tests, April 2003. Temperatures in different subsystems are shown during the execution of 6 different thermal modes.

Resurs-DK1 satellite

- **Main task:** multi-spectral remote sensing of earth's surface
- Built by TsSKB Progress in Samara, Russia
- **Lifetime >3 years (assisted)**
- Data transmitted to ground via high-speed radio downlink
- **PAMELA mounted inside a pressurized container**

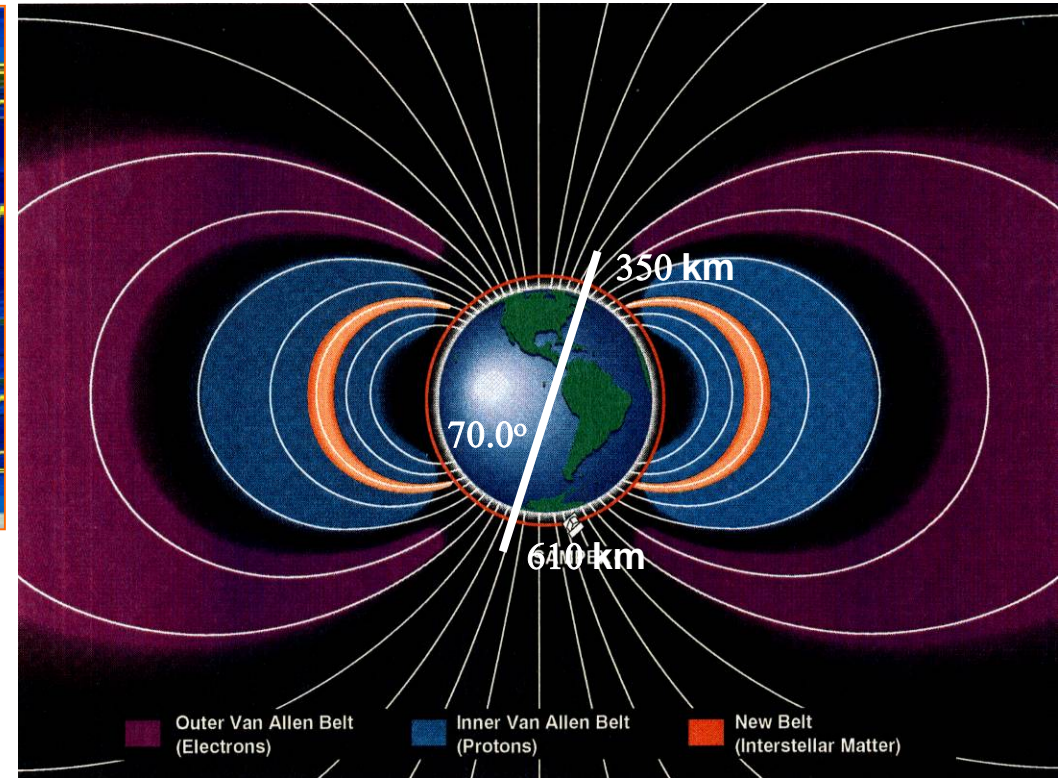

Mass: 6.7 tonnes
Height: 7.4 m
Solar array area: 36 m²

Launch: 15th June 2006, 0800 UTC

Orbit characteristics

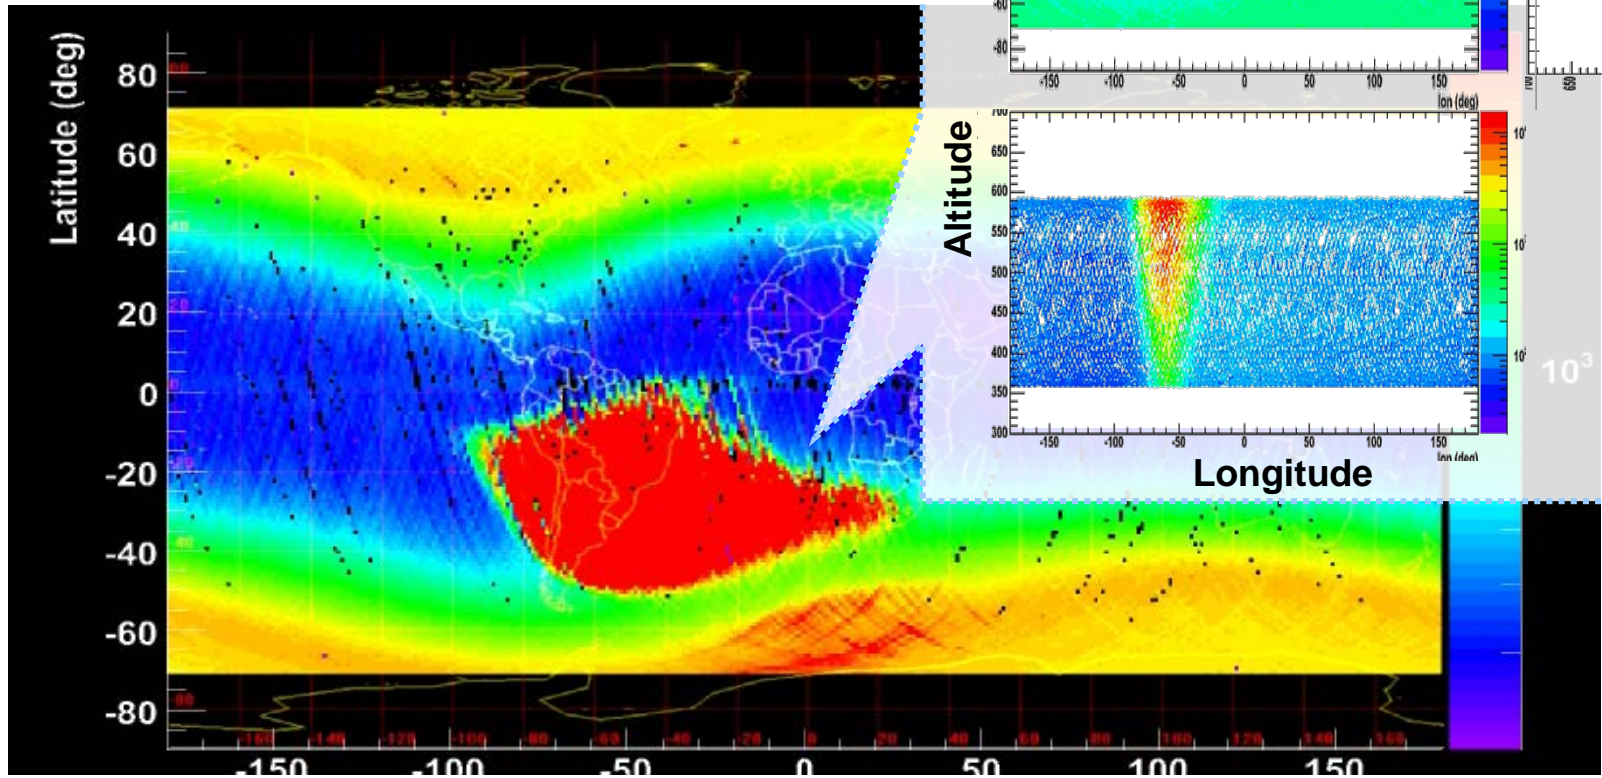

- Quasi-polar (70.0°)
- Elliptical (350 km - 600 km)
- PAMELA traverses the South Atlantic Anomaly
- At the South Pole PAMELA crosses the outer (electron) Van Allen belt

SAA morphology

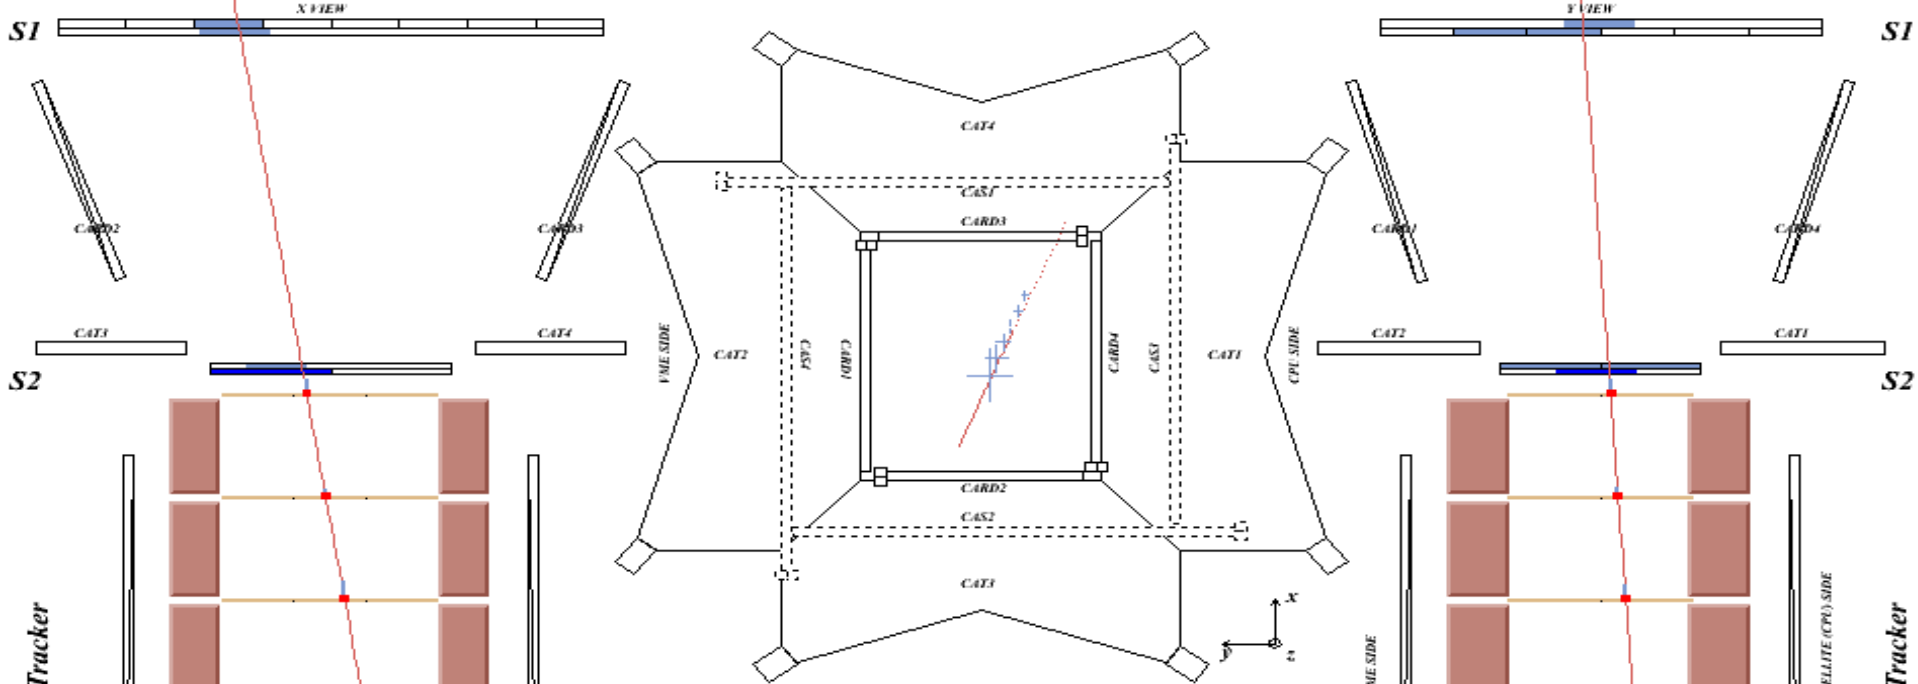

Data acquisition details

- Trigger configurations (selected by S1 counting rate):
 - **High-radiation environment**
→ (S21 AND S22) AND (S31 AND S32) + CALORIMETER
 - **Low-radiation environment**
→ (S11 OR S12) AND (S21 OR S22) AND (S31 OR S32) + CALORIMETER
- NB:
 - High voltage to PMTs, etc. is not changed during passage through SAA and radiation belts, or solar particle events.
- Average trigger rate $\sim 25\text{Hz}$
- Fraction of live time $\sim 73\%$
- Event size (compressed mode) $\sim 5\text{kB}$
→ $25\text{ Hz} \times 5\text{ kB/ev} \sim 10\text{ GB/day}$

magnitude of charge

Interaction pattern in
calorimeter:
electron-like or
proton-like, electron
energy

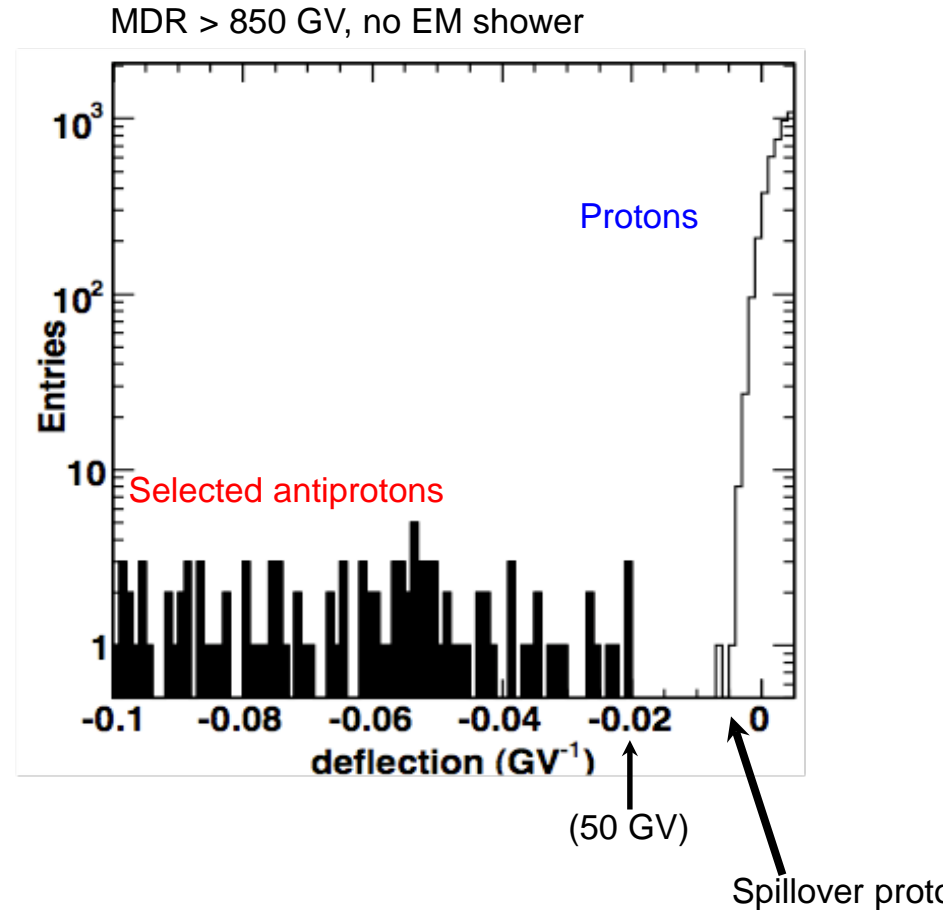

Positron
(NB: $p/e^+ \sim 10^{3-4}$)

Calorimeter Selection

Proton Background

- Spectrometer tracking information is crucial for high-energy antiproton selection
- Finite spectrometer resolution - high rigidity protons may be assigned wrong sign-of-charge
- Also background from scattered protons
- Eliminate 'spillover' using strict track cuts (χ^2 , lever arm, no δ -rays, etc)
- $\text{MDR} > 10 \times$ reconstructed rigidity
- Spillover limit for antiprotons expected to be ~ 200 GeV.

ECAL
 E of e^+ , e^- , γ

Particles and nuclei are defined by their charge (Z) and energy ($E \sim P$)

TOF
 Z, E

Magnet
 $\pm Z$

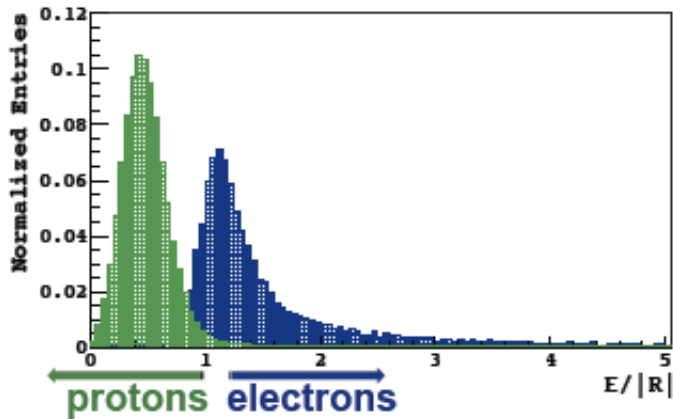

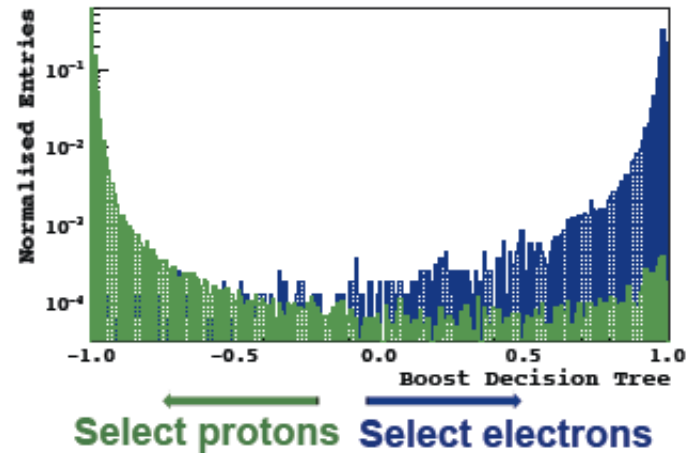

RICH
 Z, E

Z, P are measured independently by the Tracker, RICH, TOF and ECAL

AMS Positron Selection

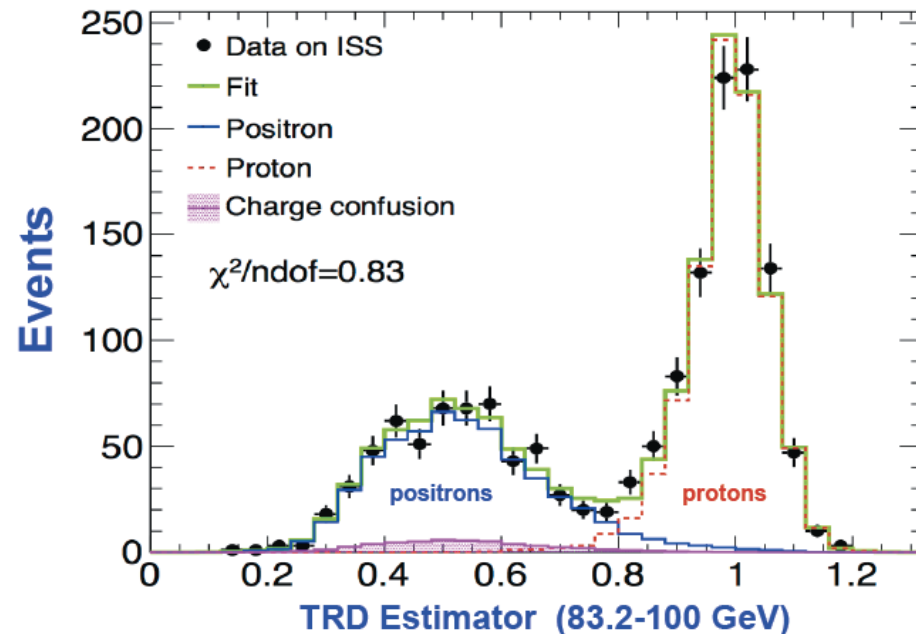

e/p separation with calorimeter+tracker

Example of Positron Selection:

The TRD Estimator shows clear separation between protons and positrons with a small charge confusion background

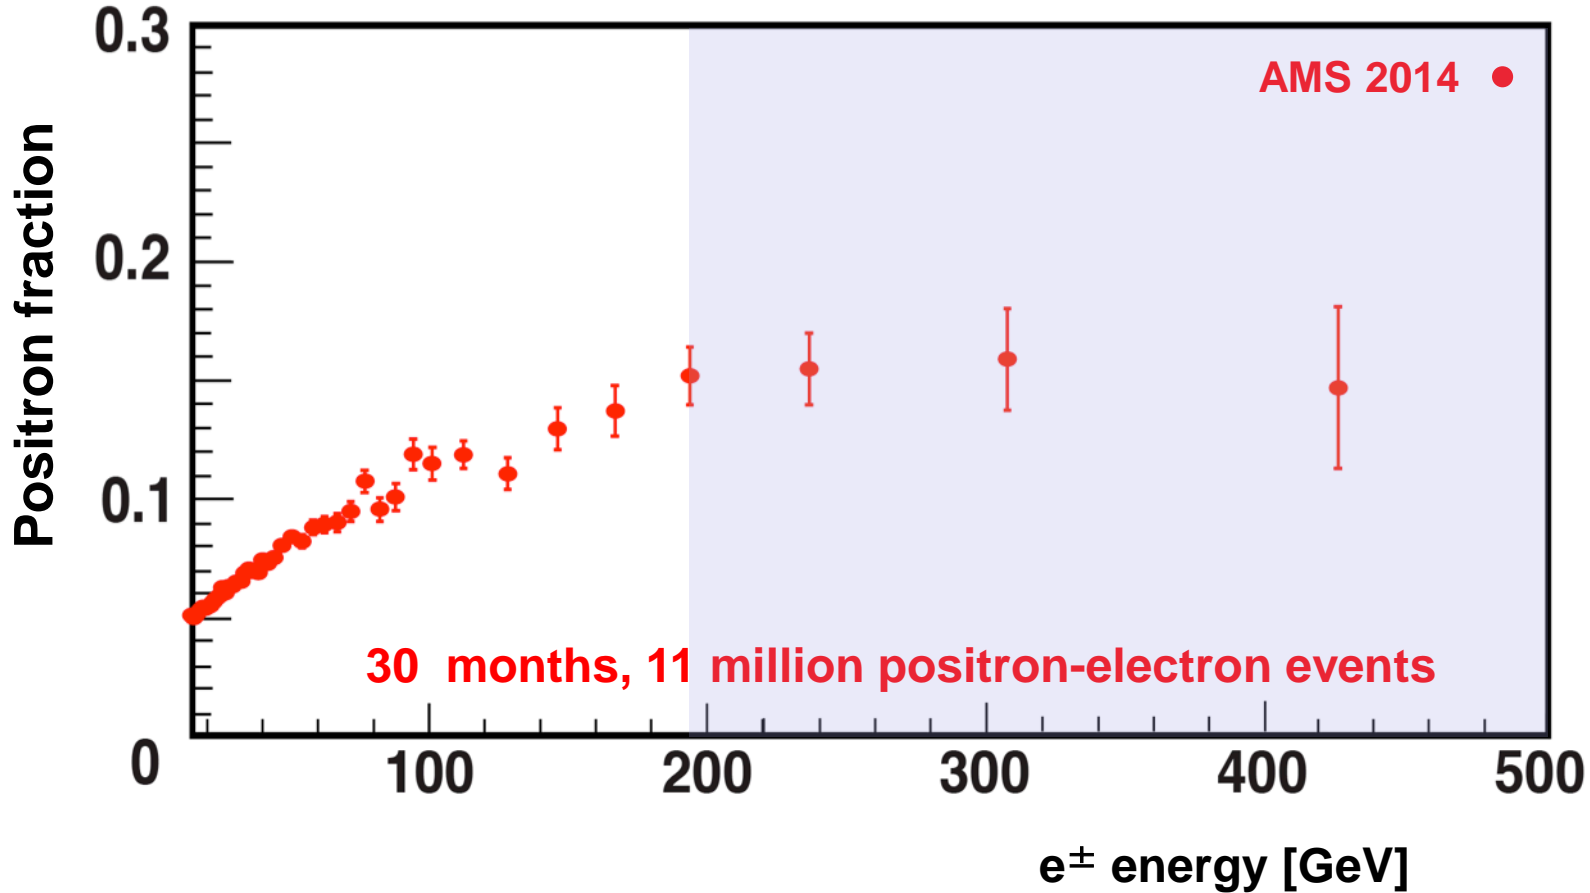

AMS Positron Fraction

2014: New Results on Positron Fraction

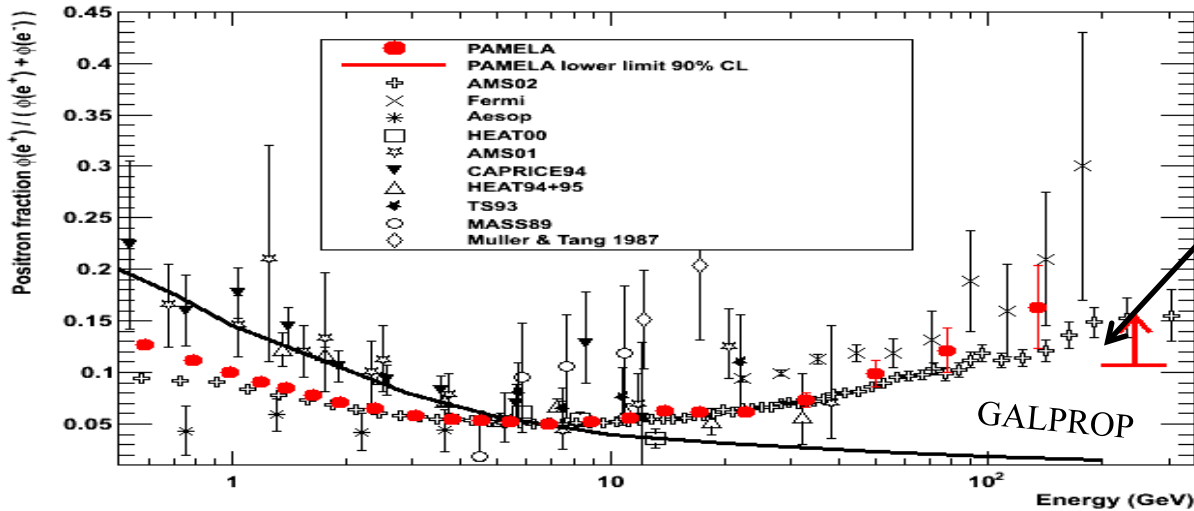

Observed flattening above ≈ 200 GeV

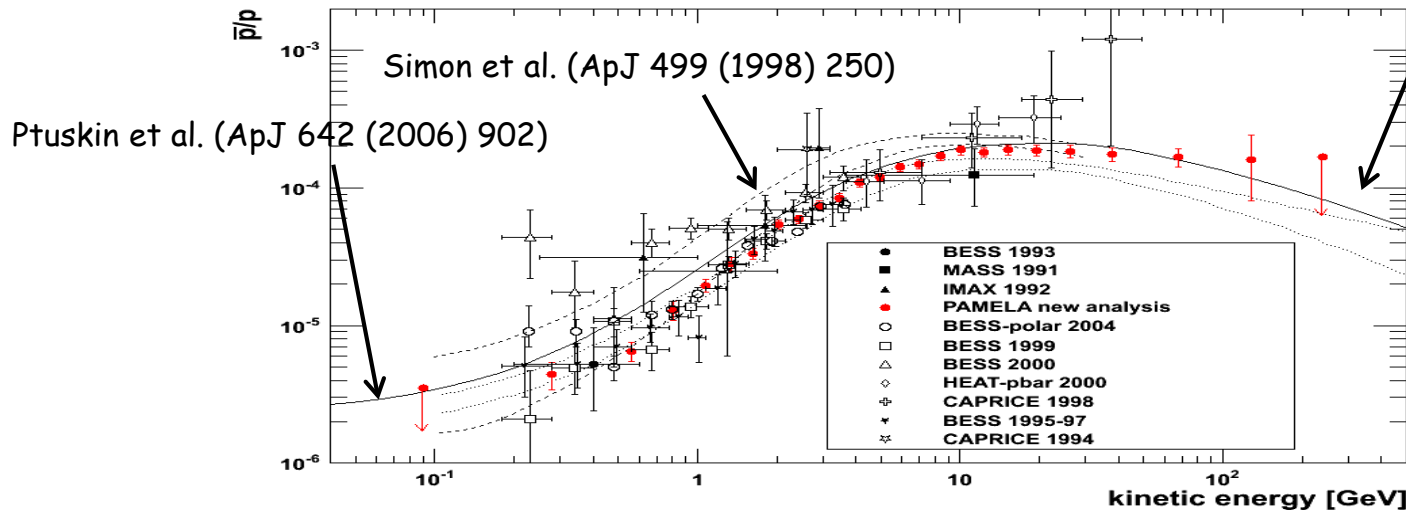

Positron Flux Data with AMS

A Challenging Puzzle for CR Physics

CR Positron spectrum significantly harder than expectations from secondary production

But antiprotons in CRs are in agreement with secondary production

Implications

A rising positron fraction requires:

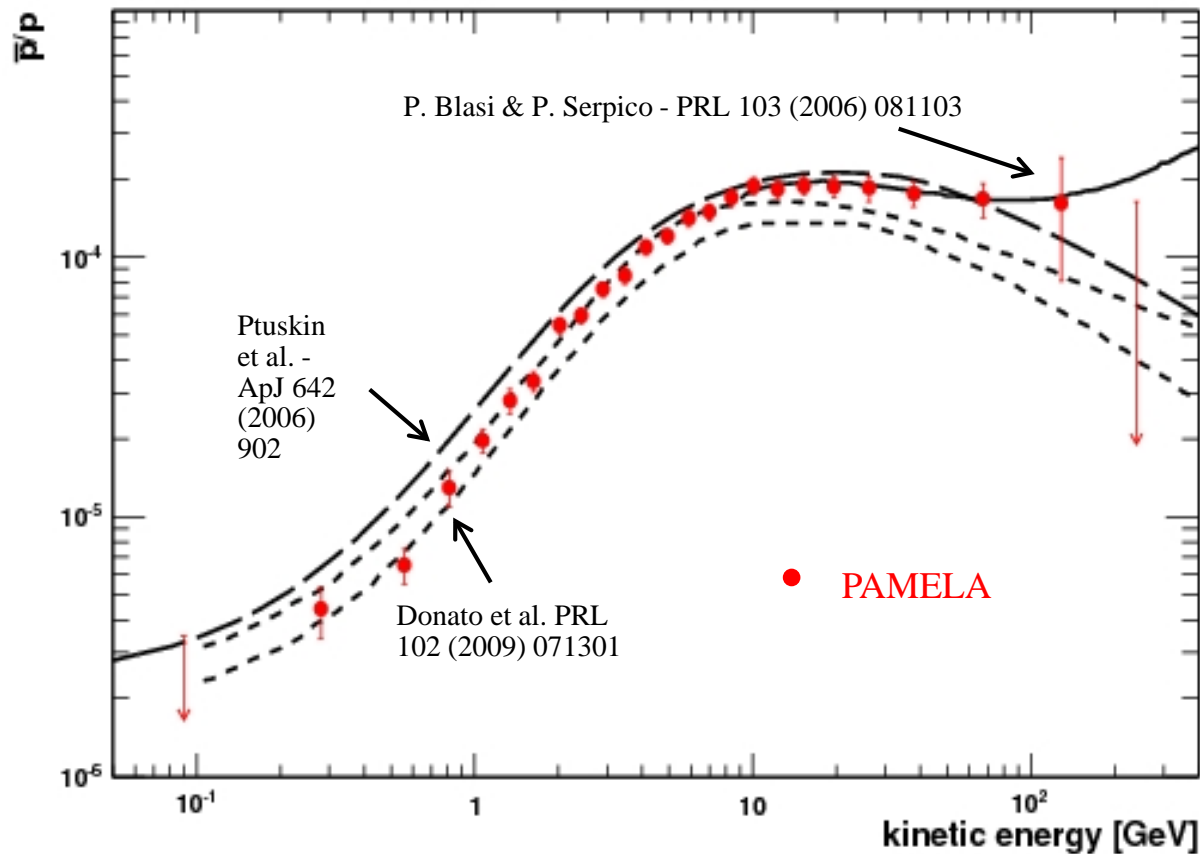

- 1. An additional component of positrons with spectrum flatter than CR primary electrons**
- 2. A diffusion coefficient with a weird energy dependence (BUT this should reflect in the CR spectrum as well)**
- 3. Subtleties of Propagation**

A Challenging Puzzle for CR Physics

P.Blasi, PRL 103 (2009) 051104 (see also Y. Fujita et al., PRD 80 (2009) 063003, M. Ahlers et al. PRD 80 (2009) 123017) Positrons (and electrons) produced as secondaries in the sources (e.g. SNR) where CRs are accelerated.

A Challenging Puzzle for CR Physics

P. Blasi, PRL 103 (2009) 051104 (see also Y. Fujita et al., PRD 80 (2009) 063003, M. Ahlers et al. PRD 80 (2009) 123017) Positrons (and electrons) produced as secondaries in the sources (e.g. SNR) where CRs are accelerated.

But also other secondaries are produced: significant increase expected in the p/p and secondary nuclei ratios.

A Challenging Puzzle for CR Physics

P. Mertsch & S. Sarkar, PRL 103 (2009) 081104

P. Blasi, PRL 103 (2009) 051104 (see also Y. Fujita et al., PRD 80 (2009) 063003, M. Ahlers et al. PRD 80 (2009) 123017) Positrons (and electrons) produced as secondaries in the sources (e.g. SNR) where CRs are accelerated.

But also other secondaries are produced: significant increase expected in the p/p and secondary nuclei ratios.

Astrophysical Explanation: Pulsars

Mechanism: the spinning B of the pulsar strips e^- that accelerated in the outer magnetosphere emit γ that produce e^\pm . But pairs are trapped in the cloud. After $(4-5) \times 10^4$ years pulsars leave remanent and pairs are liberated (e.g. P. Blasi & E. Amato, arXiv:1007.4745).

Young ($T < 10^5$ years) and nearby (< 1 kpc)
If not: too much diffusion, low energy, too low flux.

Geminga: 157 parsecs from Earth and 370,000 years old

B0656+14: 290 parsecs from Earth and 110,000 years old.

Not a new idea, e.g.: Harding & Ramaty, ICRC 2 (1987), Boulares, ApJ 342 (1989), Atoyan et al. PRD 52 (1995)

CRAB NEBULA

Pulsar Explanation

D. Hooper, P. Blasi, and P. Serpico, JCAP 0901:025,2009; arXiv:0810.1527
 Contribution from diffuse mature & nearby young pulsars.

H. Yuksel et al., PRL 103 (2009) 051101; arXiv:0810.2784v2
 Contributions of e^- & e^+ from Geminga assuming different distance, age and energetic of the pulsar

P. Blasi & E. Amato, arXiv:1007.4745
 Contribution from pulsars varying the injection index and location of the sources.

Detection prospects

DM configurations allowed by antiproton bounds

Relevant detection prospects for Dbar energies below few GeV/n, where dependence on solar modulation modeling can have an impact on the DM signal up to a factor of 2

Experimental expected sensitivities : 3σ C.L.

GAPS LDB+ : 1 detected event
 AMS : 2 detected events

- DM searches in the **antibarion** channel are crucial:
- **AntiProtons**
 - Are currently offering significant **bounds** on particle DM
 - Galactic transport has a large impact on the DM reconstruction capabilities
 - With the expected increased AMS sensitivity, nuclear uncertainties in the background calculation become a limiting factor
- **AntiDeuterons**
 - At low kinetic energies represent the signal with potentially the largest S/B ratio: “golden channel” for discovery
 - Prospects for **signal detection** both for GAPS and AMS (up to about 10 events)
 - Galactic transport and nuclear uncertainties are important, but antiD are a detection channel in a large fraction of the DM parameter space

GAPS science summary

- **Antideuterons** as DM signatures
 - **no astrophysical background** at low energy
 - **complementary** to direct/indirect searches and collider experiments
 - search for: **light DM**, heavy DM, gravitino DM,
LZP in extra-dimensions theories, (evaporating PBH)
- **Antiprotons** as DM and PBH signatures
 - precision flux measurement at ultra-low energy ($E < 0.25$ GeV)
 - **complimentary** to direct/indirect searches and collider experiments
 - **~ 10 times more statistics** @ 0.2 GeV, compared to BESS/PAMELA
 - search for: **light DM**, gravitino DM,
LZP in extra-dimensions theories,
evaporating PBH
- *Mission approved by NASA: expected to launch from Antarctica in 2020/2021*

➤ **1 LDB flight** (~35 days) -> **precision antiproton flux measurement**

~1500 antiprotons in GAPS $E < 0.25$ GeV, while 30 for BESS, 7 for PAMELA at $E \sim 0.25$ GeV

➤ **2 LDB flights** (~70 days) -> **improved antideuteron statistics**

Antideuteron sensitivity: $\sim 3.0 \times 10^{-6} [m^{-2} s^{-1} sr^{-1} (GeV/n)^{-1}]$ at $E < 0.25$ GeV

➤ **3 LDB flights** (~105 days) -> Antideuteron sensitivity: $\sim 2.0 \times 10^{-6} [m^{-2} s^{-1} sr^{-1} (GeV/n)^{-1}]$ at $E < 0.25$ GeV

Detection Prospects

Figure 1: Three 35-day GAPS flights will probe an array of representative DM models⁴⁻⁷, which predict antideuteron fluxes $\mathcal{O}(10^2 - 10^4)$ above the astrophysical background, and will be ~ 2.5 times more sensitive than predicted AMS low-energy limits (Sec. 2.3). The arrow shows the AMS geomagnetic cutoff correction size.

Unique probes for DM in extra-dimensions and evaporating PBHs

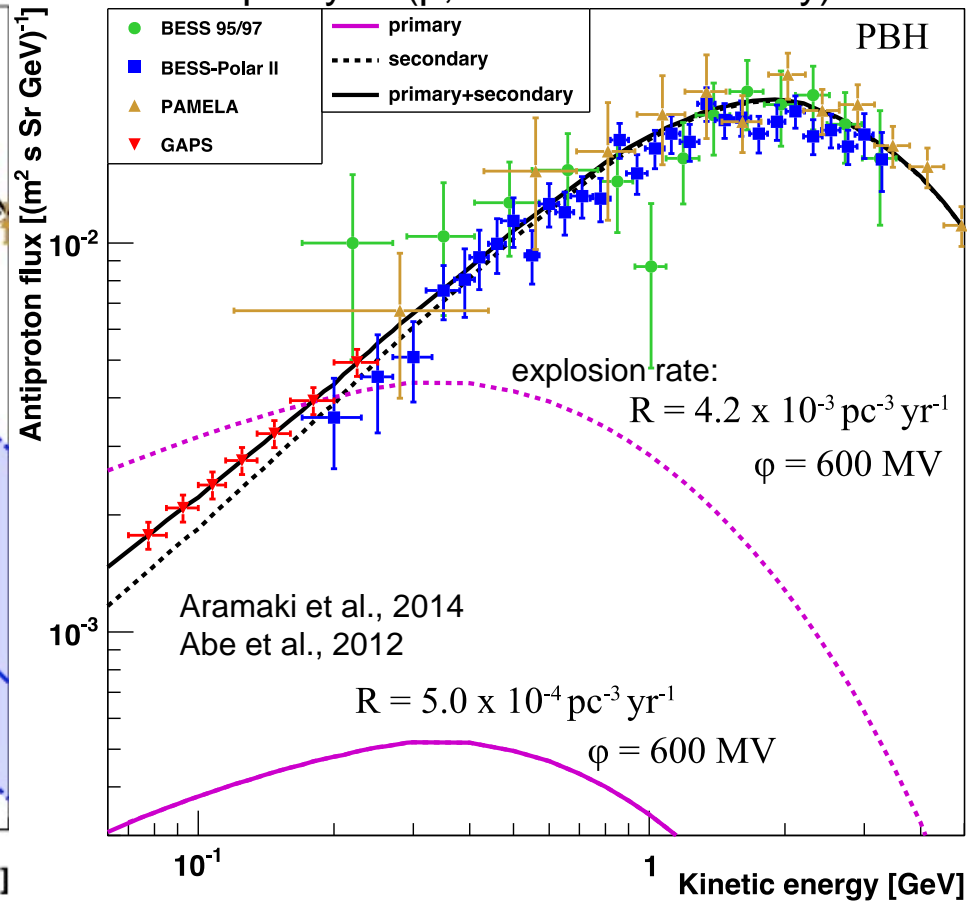

LZP

- Lightest Z_3 charged particle
- stable under Z_3 symmetry
- right-handed neutrino

Primordial Black Hole Evaporation

- density fluctuations, phase transitions, collapse of cosmic strings in the early universe
- $R < 0.02\text{-}0.05 \text{ pc}^{-3} \text{ yr}^{-1}$ (γ , Fermi, EGRET)
- $R < 0.0012 \text{ pc}^{-3} \text{ yr}^{-1}$ (ρ , BESS-Polar II only)

GAPS detects atomic X-rays and annihilation products from exotic atoms

Plastic Scintillator TOF

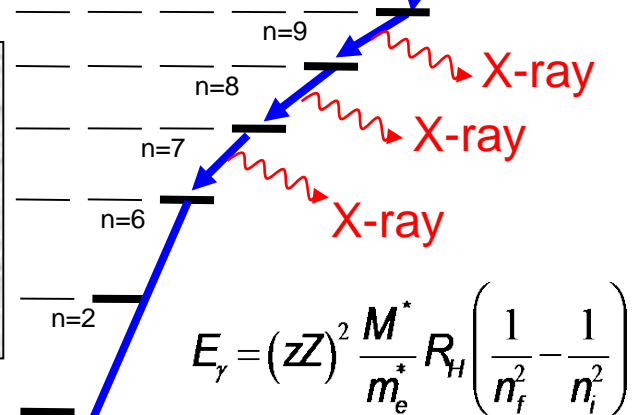

Si(Li) Target/Detector

Atomic Transitions

Exotic Atom

A time of flight (TOF) system tags candidate events and records velocity

The antiparticle slows down & stops in a target material, forming an excited exotic atom

Deexcitation X-rays provide signature

Annihilation products provide added background suppression

Nuclear Annihilation

X-ray yields were measured at KEK in 2004 and 2005

GAPS instrument summary

TOF plastic scintillators

- outer TOF: 3.6m x 3.6m, 2m height
- inner TOF: 1.6m x 1.6m, 2m height
 - 1m b/w outer and inner TOFs
 - 500 ps timing resolution
 - 16.5 cm wide plastic paddles
 - PMT on each end

Science weight: ~1700 kg, 34H balloon

Si(Li) detectors

- 10 layers, 1.6m x 1.6m
- layer space: 20 cm
- Si(Li) wafer (~1500 wafers)
 - 4 inch diameter
 - 2.5mm thick wafer
 - 12 x 12 rectangular
- segmented into 4 strips
 - 3D particle tracking
- timing resolution: ~ 100 ns
- energy resolution: 3 keV
- operation temperature: -35 C
- dual channel electronics
 - X-ray: 20 - 80 keV
 - charged particles: 0.1 - 100 MeV

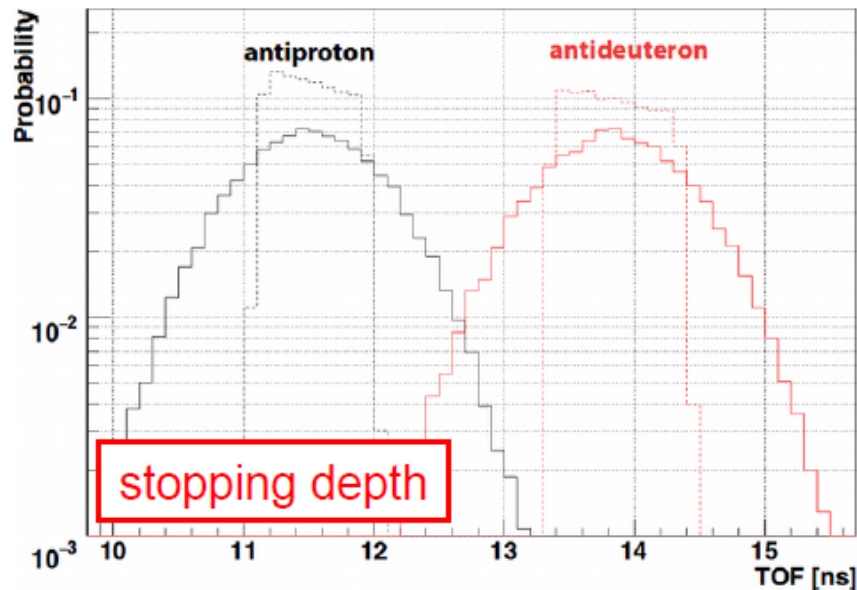

Cooling system

- oscillating heat pipe (OHP)
- demonstrated in pGAPS

GAPS sensitivity

Astropart. Phys. 74, 6 (2016)

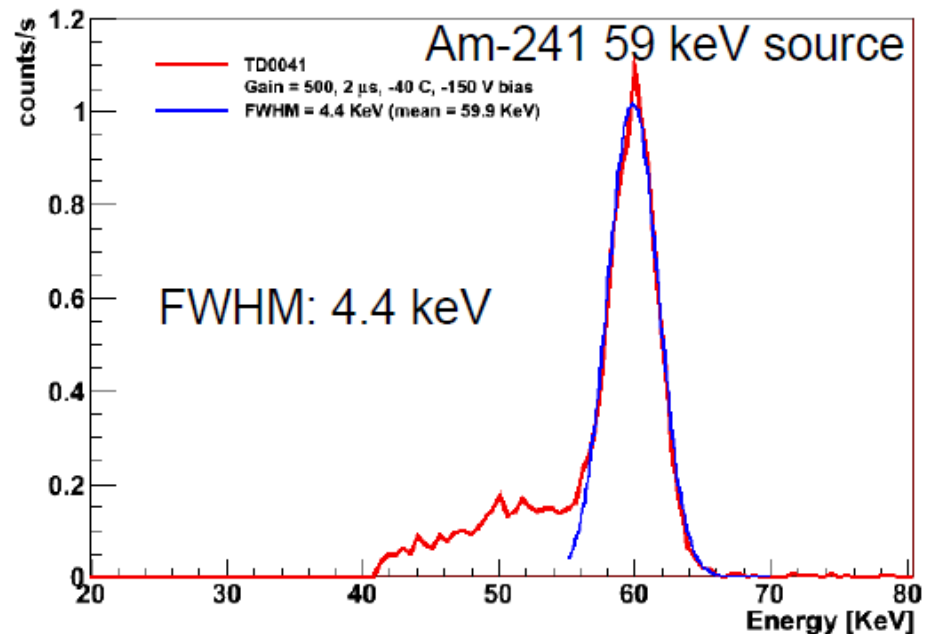

Background rejection:

- stopping protons do not have enough energy to produce pions and cannot form exotic atoms (positive charge)
- deexcitation X-rays have characteristic energies
- number of annihilation pions and protons depends on mass of antiparticle
- stopping depth in detector

Si(Li) detector production

- GAPS will use 1350 4" Si(Li) detectors, 2.5mm thick
- fabrication scheme developed at Columbia U.
- plan is to have detectors produced by private company Shimadzu, Japan
- leakage current $\sim 15\text{nA}$ at -30C
- confirmed performance with cosmic rays (MIPs) and Am-241 source (X-rays)
- already achieved 4.4 keV FWHM at 59 keV
- Si(Li) detector fabrication: NSS/MIC 2013 IEEE 1-3, (2013)

INFN Contribution

- Design, development and production of the ASIC for the read-out of the Si(Li) detectors

INFN Contribution

Objective: read out 2.5 mm thick, 1" diameter Si(Li) detectors [$C_D \approx 75$ pF, $I_{LEAK} = O(1$ nA)]

Requirements:

- dynamic range of 50 MeV, minimum signal ≈ 20 keV
- energy resolution of 4 keV FWHM at the lower end (goal of 3 keV FWHM)
- interface to already available discrete preamplifier

Available design choices and optimization opportunities:

- Selection of the CMOS technology (at present all electronics is discrete)
- Investigate the possibility to integrate the preamplifier
- ASIC architecture (shaper, peak detector vs S/H, multiplexing, internal digitization?)

INFN Contribution

- Design, development and production of the ASIC for the read-out of the Si(Li) detectors
- Design and development of the HV Power Supply System for the Si(Li) detectors.

Successful prototype (pGAPS) flight in 2012 @ Taiki, JAXA balloon facility in Japan

- ✓ First balloon experiment with Si(Li) detectors
- ✓ TOF performance test and measure cosmic-ray proton count rate
- ✓ Demonstrate cooling system

- 6 commercial Si(Li) detectors
- 3 TOF layers, 50cm x 50cm, ~ 50cm separation

M. Hailey, Dark Matter
2014, UCLA

Commercial SEMIKON Si(Li)
4 inch diameter, 2.5mm thick

TOF paddle
with PMT, LG
16.5 cm wide

Vessel for
DAQ

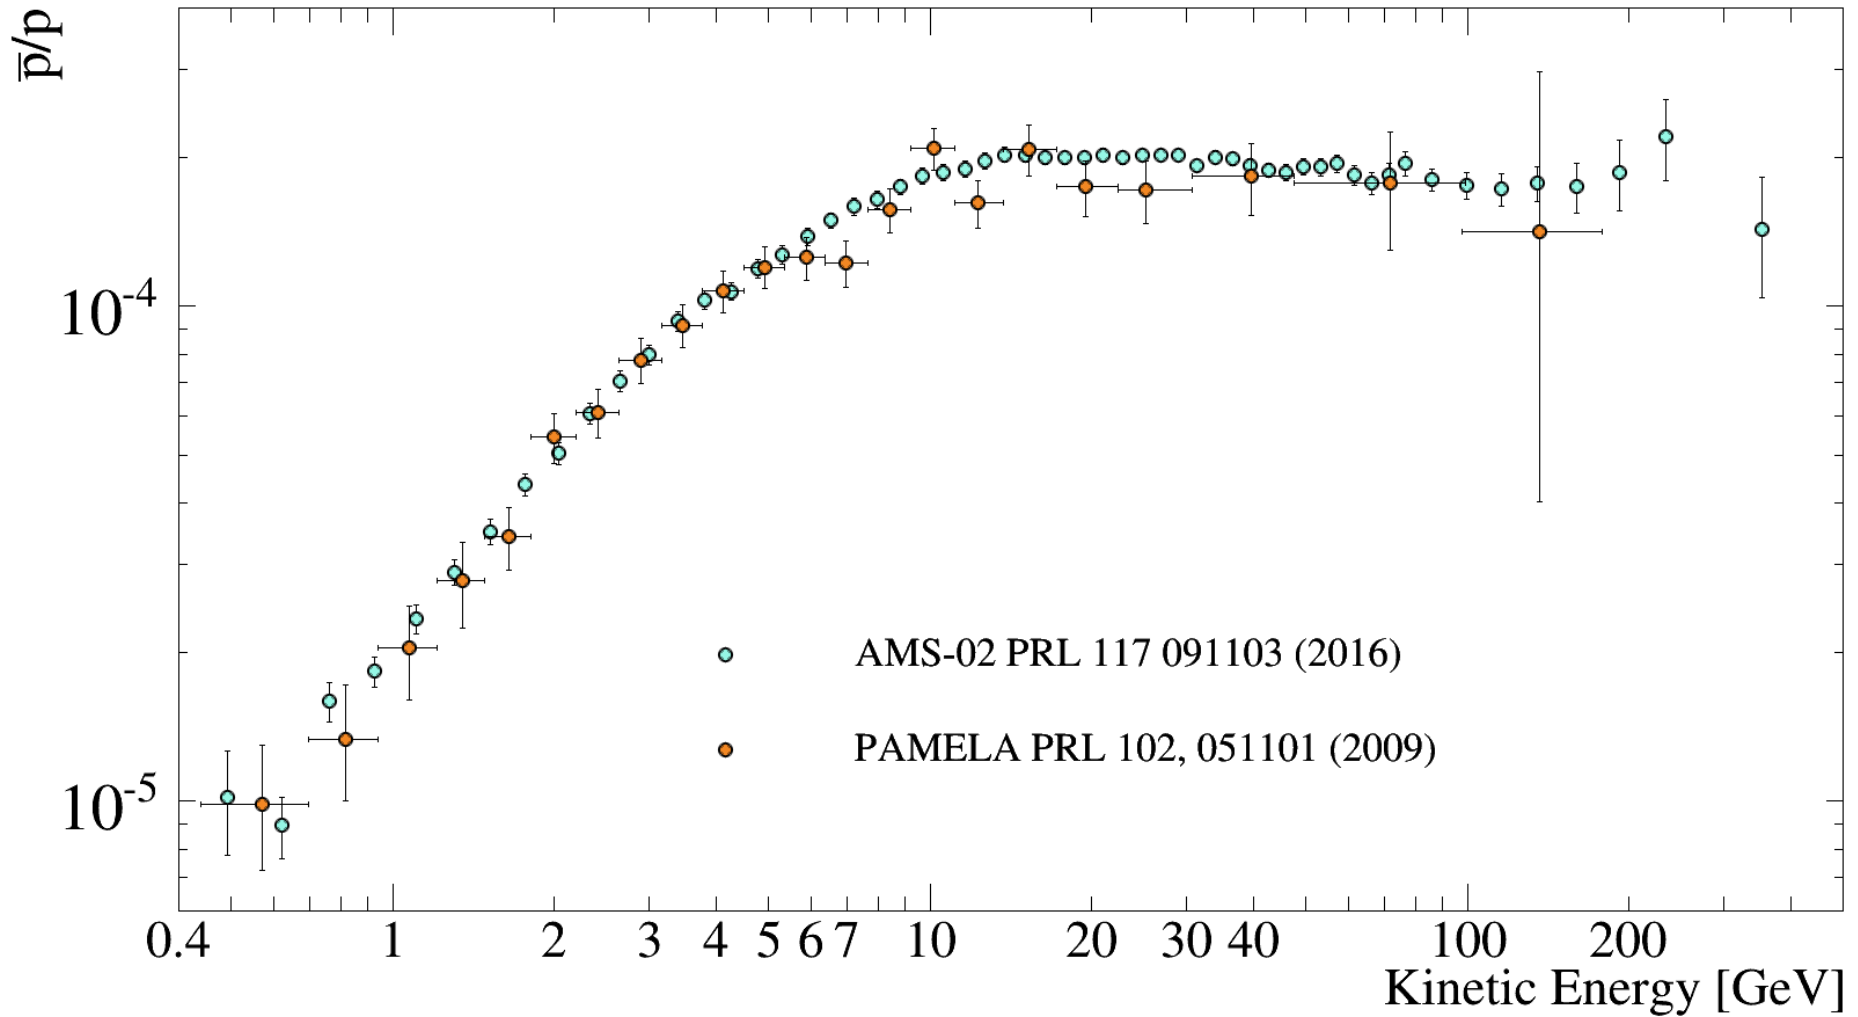

Si(Li) detector
surrounded by TOF

Conclusions

The first historical measurements on galactic
antiprotons

Conclusions

Thanks!
