

# Investigating the role of photoemission in the e-cloud formation at the LHC

Philipp Dijkstal

04.06.2018

Many thanks to my former colleagues at CERN

G. Iadarola, L. Methner, A. Romano, G. Rumolo, G. Skripka

Thanks to my superiors at PSI

S. Reiche, T. Schietinger and D. Kiselev

## Contents

# Investigating the role of photoemission in the e-cloud formation at the LHC

## Electron cloud build-up simulations

- Modelling of photoemission

- Published photoemission measurements

- Simulation results with photoemission

## Comparison to measured heat loads

- LHC arcs

- LHC special instrumented cells

## Summary

## Photoelectrons in the LHC

↔ How many photoelectrons?

↔ How are photoelectrons distributed in the chamber?

↔ In simulations, what is the effect on the heat load or strength of the electron cloud?

Relevant CERN note: CERN-ACC-NOTE-2017-0057 <https://cds.cern.ch/record/2289940>

## Emitted photons by a proton beam in the LHC

Plots for LHC bending radius (Formulas in photoemission note):

- ▶ Photon spectrum
- ▶ Power spectrum
- ▶ Number of photons higher than the Cu work function per proton and meter bend
- ▶ Share of photons above the Cu work function w.r.t. all photons

↪ Also calculate total power of synchrotron radiation, which loads the cooling systems

↪ 7 and 6.5 TeV look relatively similar

## Modelling of photoelectrons in PyECLOUD

- ▶ The number of photons emitted by the beam can be calculated
- ▶ Absorption of electrons and the number of photoelectrons depends on surface properties
- ▶ Photoelectron generation in parallel to the beam charge

### PyECLOUD input:

- ▶ total number of photoelectrons to generate
- ▶ share of photoelectrons created by reflected photons
- ▶ spatial distribution of reflected photons

### Used parameters

- ▶ Literature review of published measurement campaigns from 1998-2004

- └ Electron cloud build-up simulations
- └ Published photoemission measurements

## Published measurement results - yields

- ▶ Baglin, Collins, Gröbner: "Photoelectron yield and photon reflectivity from candidate LHC vacuum chamber materials with implications to the vacuum chamber design" (1998) - LHC Project Report 206
- ▶ Measurements at EPA at CERN
- ▶ Measure **Yield per incoming photon  $Y$** , **Reflectivity  $R$**  and calculate **Yield per absorbed photon  $Y^* = \frac{Y}{1-R}$**
- ▶ Only reflectivity in forward direction
- ▶ Measurements only valid for the employed photon spectrum

		7 TeV		11.5 TeV	
		45 eV		194 eV	
Surface	Status	R (%)	Y* (e/ph)	R (%)	Y* (e/ph)
Cu	as-received	80.9	0.114	77.0	0.318
co-lam.	air baked	21.7	0.096	18.2	0.180
Cu elect.	as-received	5.0	0.084	6.9	0.078
Cu	as-received	1.8	0.053	-	-
sawtooth	150°C, 9h	1.3	0.053	1.2	0.052
	150°C, 24h	1.3	0.040	1.2	0.040

↔ Use these yields for conservative estimate

↔ Scale from 7 TeV to 6.5 TeV with number of photons with energy higher than the Copper work function

- └ Electron cloud build-up simulations
- └ Published photoemission measurements

## Published measurement results - surface conditioning

- ▶ Baglin, Collins, Gröbner, Grünhagel: "Measurements At EPA Of Vacuum And Electron-Cloud Related Effects" (2001) - 11th Chamonix Workshop (CERN-SL-2001-003)
- ▶ Measurements at EPA at CERN
- ▶ Measure  $Y$ ,  $R$  and calculate  $Y^* = \frac{Y}{1-R}$
- ▶ Only reflectivity in forward direction
- ▶ Measurements only valid for the employed photon spectrum
- ▶ Estimate effect of photon scrubbing

### Sawtooth Cu

	45 eV		194 eV	
Dose (ph/m)	R (%)	Y* (e/ph)	R (%)	Y* (e/ph)
$\sim 2 \cdot 10^{19}$	8	0.029	7	0.040
$1.5 \cdot 10^{22}$		0.015		0.022

↪ Only results from sawtooth material are published

↪ Sharp decrease in yields

↪ Use these yields ( $\sim 50\%$ ) for optimistic estimate

↪ Also scale the yields from non-sawtooth materials by the same factor

## Published measurement results - reflectivities

- ▶ Mahne, Baglin, Collins et al.: "Photon reflectivity distributions from the LHC beam screen and their implications on the arc beam vacuum system" (2004) - LHC Project Report 668
- ▶ Measurements at ELETTRA in Italy
- ▶ Measure reflectivities only, but in all directions and for different photon energies

	Flat sample	Saw-tooth sample
Forward scattering (%)	80	4
Back scattering (%)	0	2
Diffused (%)	2	4
Total	82	10

↪ Use these reflectivities and recalculate  $Y^* = \frac{Y}{1-R}$

↪ After doing calculation, 20% share of reflected photoelectrons

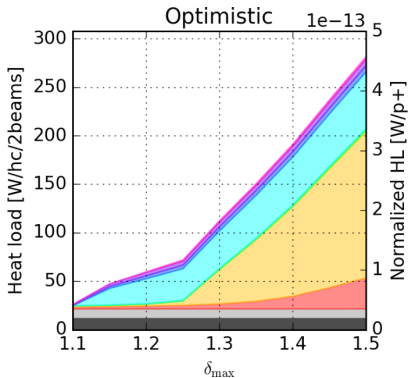

## Explanation of plot

- └ Electron cloud build-up simulations
- └ Simulation results with photoemission

## Explanation of plot

## Simulation results

- ▶ An initial distribution of electrons was used for simulations without seeding mechanism
- ▶ Uniform distribution of photoelectrons generated from reflected photons ( $\sim 20\%$ )
- ▶ Reminder:
  - "Conservative"  $\leftrightarrow$  as-received surface
  - "Optimistic"  $\leftrightarrow$  after photon scrubbing in the lab
  - "Disabled"  $\leftrightarrow$  Initial electron distribution, no seeding mechanism

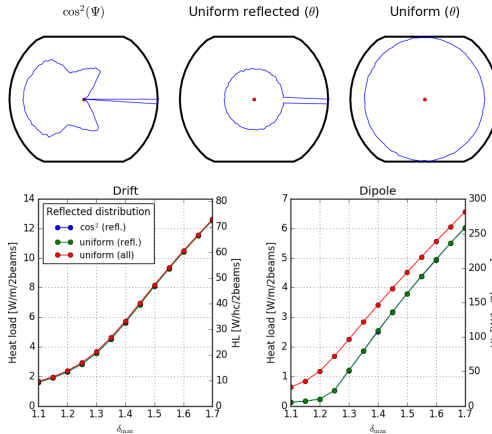

- $\hookrightarrow$  Only drifts and dipoles are sensitive to the presence of photoelectrons
- $\hookrightarrow$  Quadrupoles and higher order magnets are not sensitive

- └ Electron cloud build-up simulations
- └ Simulation results with photoemission

## Influence of spatial distribution

- Spatial distribution only matters in the dipolar magnetic field (for LHC chamber and simulation parameters)

- └ Electron cloud build-up simulations
  - └ Simulation results with photoemission

## Time-continuous photoemission

- In PyECLOUD, the photoelectrons are usually generated in parallel with the beam charge
- A time-continuous generation of photoelectrons does not change the results (for LHC chamber and simulation parameters)

## Comparison to measured heat loads (more details in talk of G. Iadarola)

- ▶ Simulations: **25 ns case** and different photoemission parameters
- ▶ Reminder: "Conservative"  $\leftrightarrow$  as-received surface, "Optimistic"  $\leftrightarrow$  after photon scrubbing in the lab
- ▶ Difference of 20%-30% going from no photoelectrons to "conservative" estimation.

## Comparison to measured heat loads (more details in talk of G. Iadarola)

6.5 TeV

(450 GeV)

6.5 TeV

- ▶ Variations between cells are larger than simulated impact of photoemission seeding
- ▶  $\delta_{\max}$  of  $\sim 1.15$  compatible with low heat load cells
- ▶  $\delta_{\max}$  of  $\sim 1.32$  compatible with high heat load cells
- ▶ Also higher heat load from impedance and synchrotron radiation at high energy

## Special instrumented cells - Dipoles

Special cells Fill 5433

- ▶ Large differences in measured heat loads
- ▶ Reminder: also higher heat load from impedance and SR

## Special instrumented cells - Quadrupoles

Special cells Fill 5433

- ▶ Large differences in measured heat loads, again!
- ▶ Overall less effect of photoelectrons than in dipoles
- ▶ But higher total EC heat load, consistent with simulations
- ▶ Strong magnetic field changes e-cloud dynamics and suppresses photoelectron contribution

## Summary

- ▶ Measurements of LHC beam screen materials were shown
- ▶ PyECLOUD simulation parameters were explained and deduced
- ▶ Simulation results with and without seed electrons from photoemission were shown
- ▶ The impact is at the level of 20% - 30%, mostly because of drift spaces
- ▶ Simulation results were compared with measured heat loads from the LHC

## Summary

- ▶ Measurements of LHC beam screen materials were shown
- ▶ PyECLOUD simulation parameters were explained and deduced
- ▶ Simulation results with and without seed electrons from photoemission were shown
- ▶ The impact is at the level of 20% - 30%, mostly because of drift spaces
- ▶ Simulation results were compared with measured heat loads from the LHC

### Some further notes

- ▶ Photon spectra change with beam energy
- ▶ Published measurement results were for 7 TeV LHC radiation
- ▶ More measurements necessary to make predictions for e.g. FCC

Thank you for your attention
