

# Scientific highlights and status of the MAGIC Telescope

## Outline:

- Introduction
- Galactic observations
- Extragalactic observations
- Dark matter searches
- MAGIC-II

Marcos Lopez  
INFN/Padova

# The MAGIC Collaboration

**Collaboration: ~ 150 Physicists, 23 Institutes, 12 Countries:**

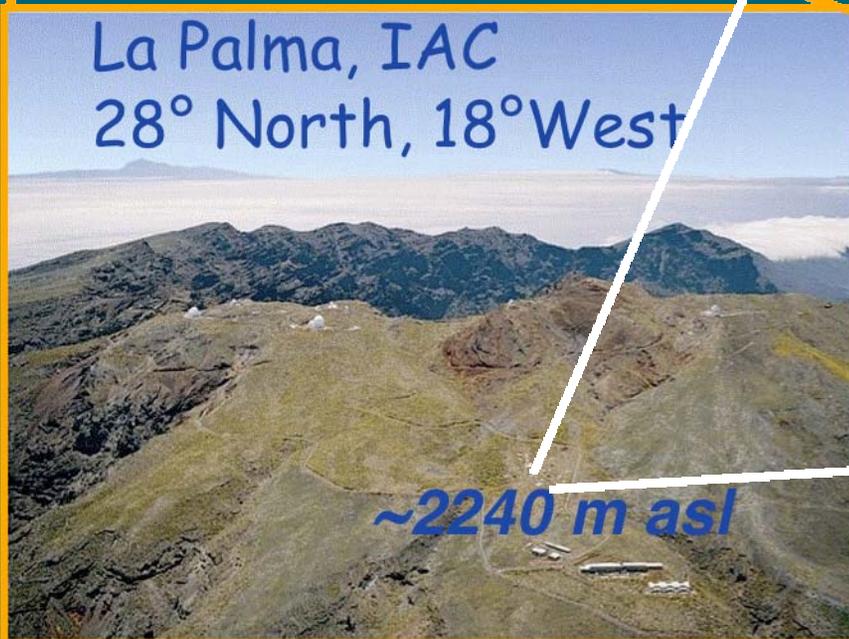

Instituto de Astrofísica de Andalucía, IFAE, UBarcelona, UBarcelona,  
DESY Zeuthen, Instituto de Astrofísica Canarias, INAF Rome,  
Croatian MAGIC consortium, University C. Davis, University Dortmund,  
Institut de Ciències de l'Espai, University Lodz, UCM Madrid, MPI Munich, INFN/  
University Padua, INFN/ University Siena/Pisa, Institute for Nuclear  
Research Sofia, Tjorla Observatory,  
Yerevan Institute,  
INFN/University Udine,  
University Würzburg,  
ETH Zürich

**Goal: Achieve the lowest energy threshold in the world**

*Close unexplored gap between space and  
ground-based gamma telescopes*

# The MAGIC telescope

MAGIC

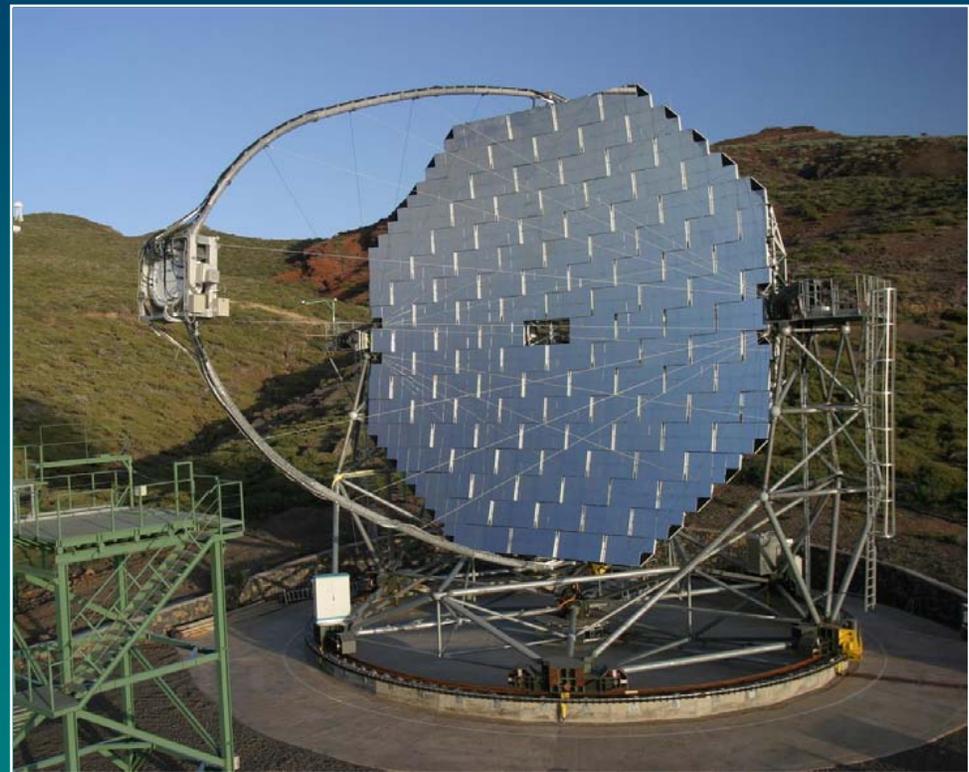

Scineghe 09, Assisi

# The MAGIC telescope

- Largest single dish CT:  
17 m  $\varnothing$  mirror dish (241 m<sup>2</sup>)
- Camera with 577 enhanced QE PMT's, 3.5° FoV
- Ultra-light carbon fibre frame:
  - Fast repositioning for GRBs: average < 40 s
- Enhanced duty cycle (by 50%) thanks to moonlight & twilight observations
- Performance:
  - Low energy threshold:
    - ❖ Std: 55 GeV
    - ❖ Sumtrigger: 25 GeV
  - Sensitivity: 1.6% Crab/50h
  - Angular resolution: ~ 0.1°
  - Energy resolution: 20-30%

*In regular observation mode since fall 2004*

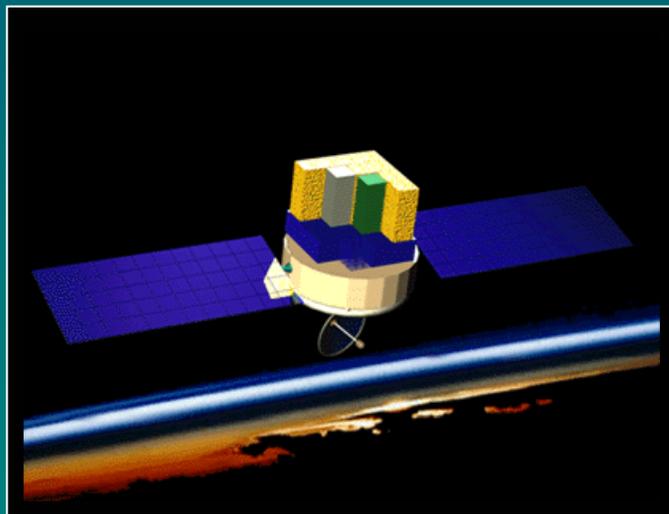

# Basic fact: $\gamma$ -rays absorbed in atmosphere

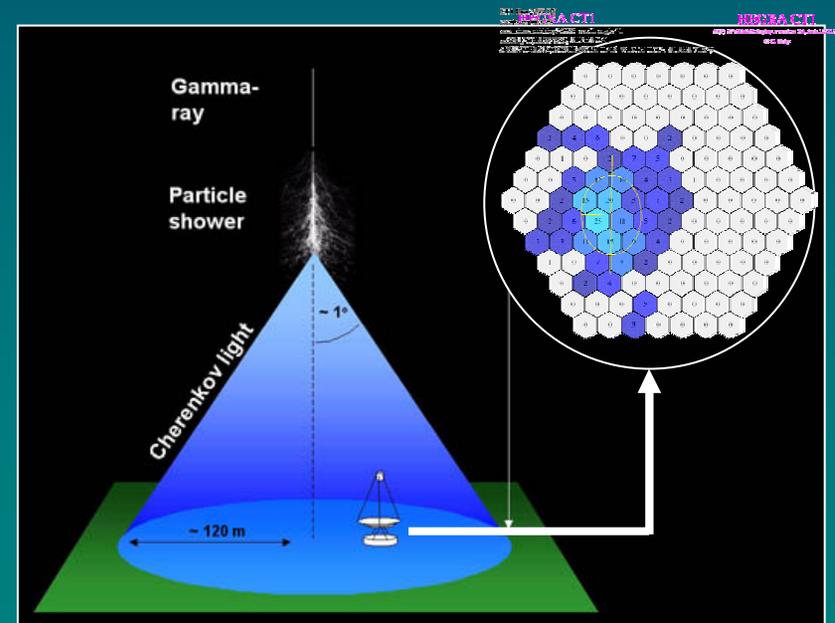

## Satellites

- **Direct detection**
- Small background
- Small Effective Area  $\sim 1\text{m}^2$

## Ground Detectors

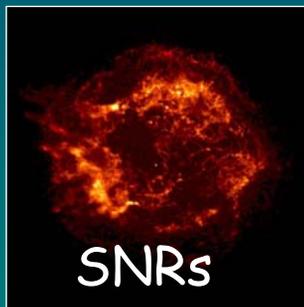

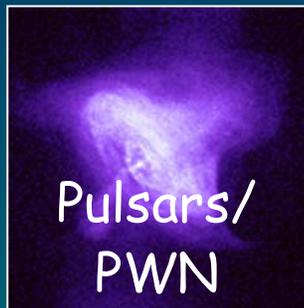

- **Indirect detection**
- Huge Effective Area  $\sim 10^5\text{m}^2$
- Enormous hadronic background

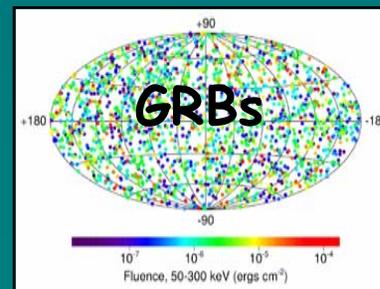

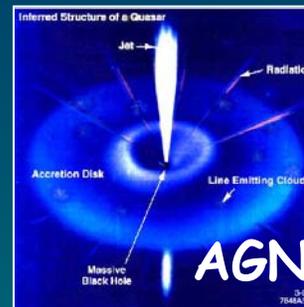

# MAGIC Physics Targets

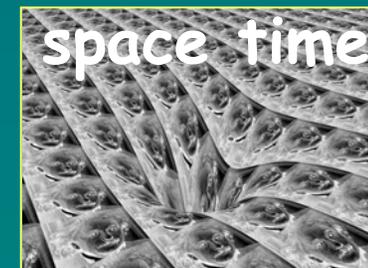

## Galactic

## Extragalactic

## Fundamental Physics

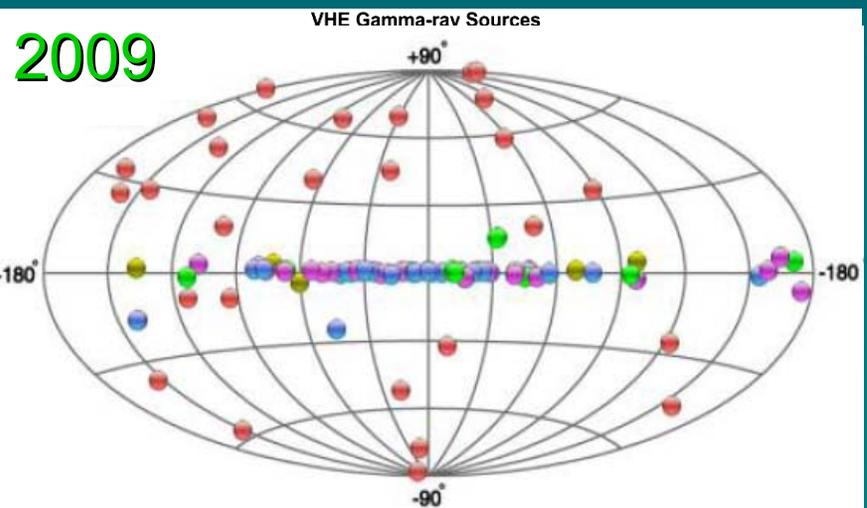

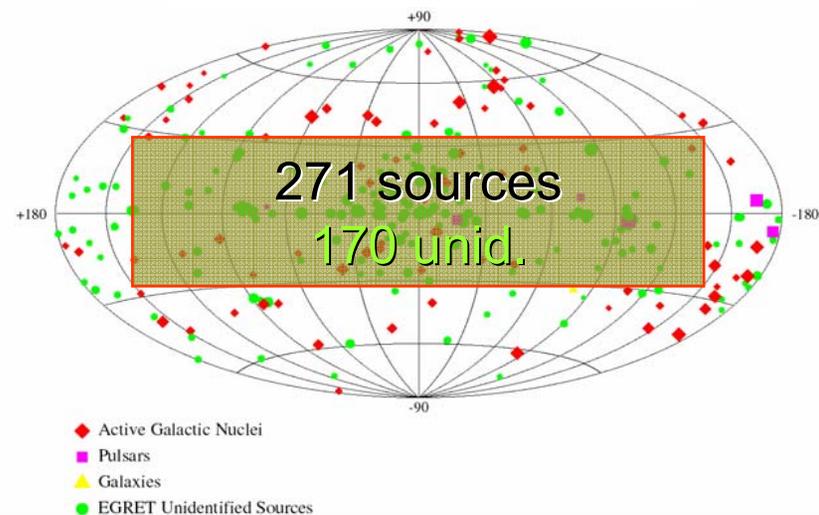

# The $\gamma$ -ray sky

- EGRET gave a nice crowded picture of energies up to 10 GeV.
- Ground-based experiments show very few sources **In spite of having much better sensitivity!**
- Situation dramatically changed thanks to the new generation of CTs

THIRD EGRET CATALOGUE OF GAMMA-RAY POINT SOURCES

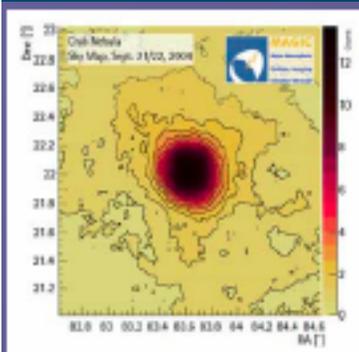

100 MeV < E < 10 GeV

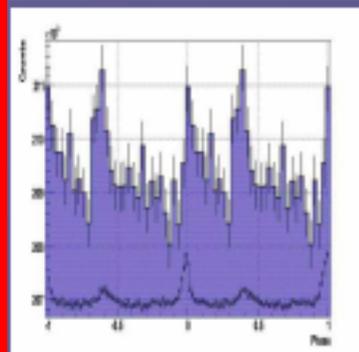

# Highlights in MAGIC galactic observations

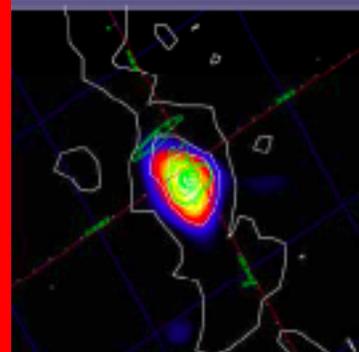

4 discoveries, 6 more detected, U.L on many others

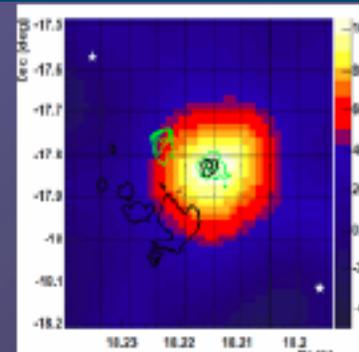

Crab Nebula

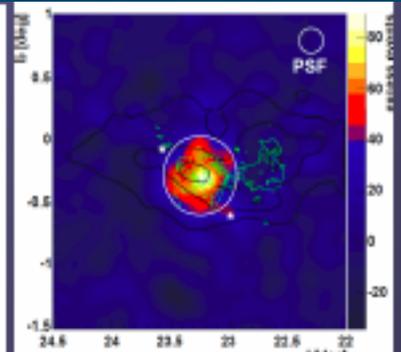

Discovery after  
20years of effort

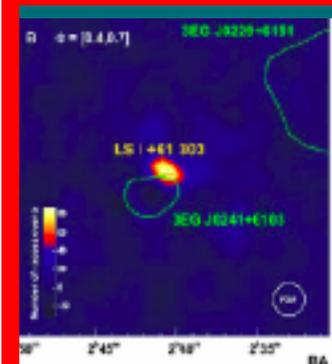

Galactic Center

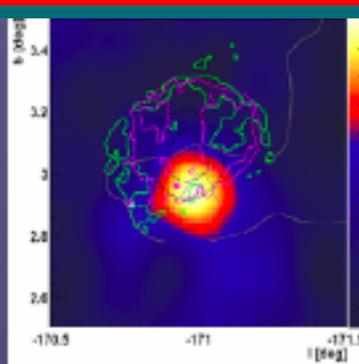

HESS J1813

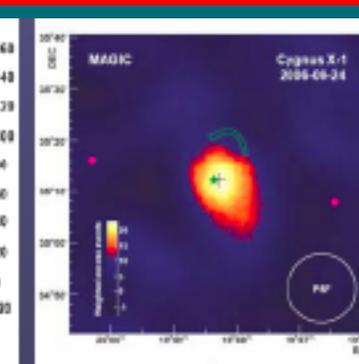

HESS J1834

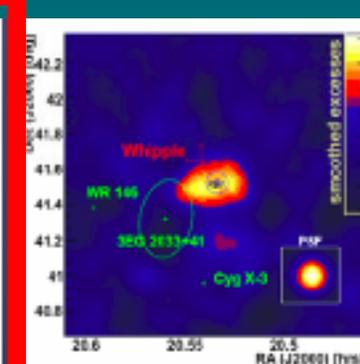

LSI+61 303

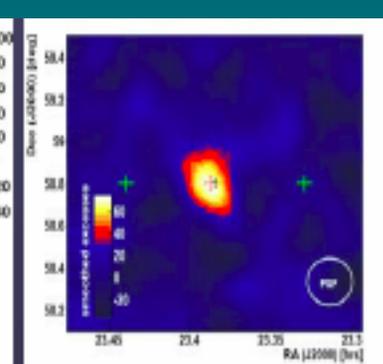

IC443

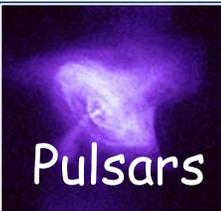

Cyg X-1

TeV 2032

Cas-A

Pulsars

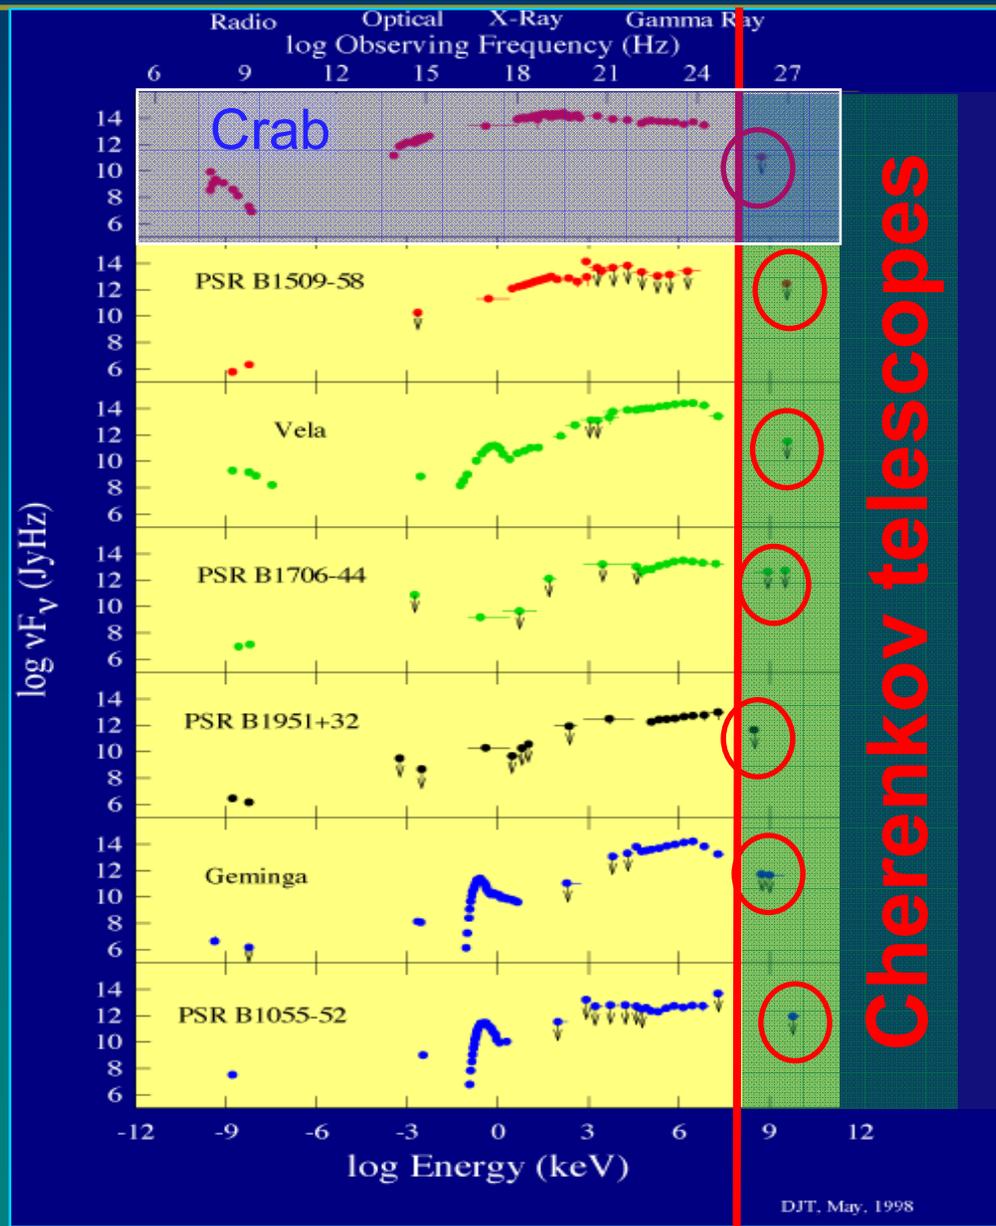

# Pulsars visible in VHE $\gamma$ -rays?

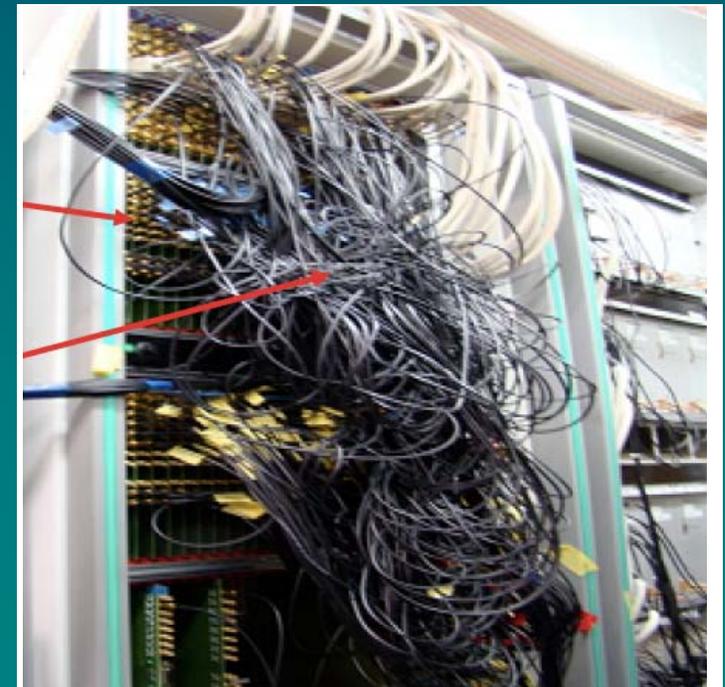

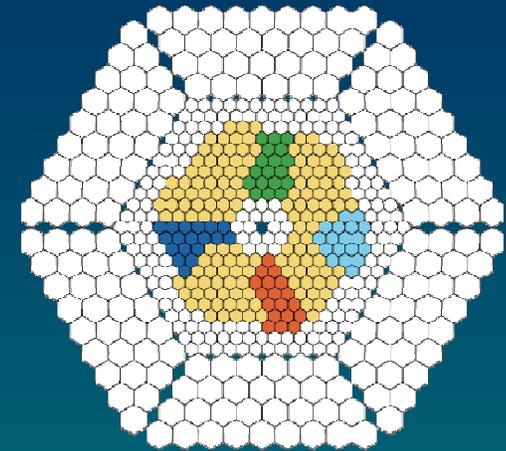

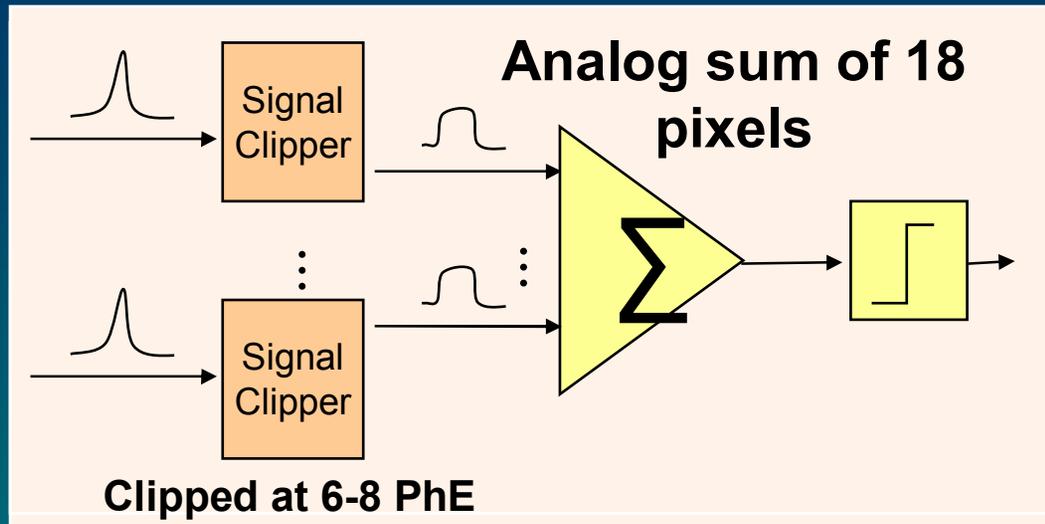

MAGIC

- Maximum of emission at hard X- and  $\gamma$ -ray
- Spectra are very different above 1 GeV  
*High energy spectral cutoffs*
- Observational challenge since 20 years
- Instrument with sensitivity well below 100 GeV needed

Scineghe 09, Assisi

## MAGIC SumTrigger

- 24 Clusters of 18 pixels in a ring area
  - Add analog signals from a cluster & discriminate on summed signal
  - Problem: Large amplitude from Afterpulses
    - Solved by clipping signal
  - Built in summer 2007
- Scineghe 09, Assisi

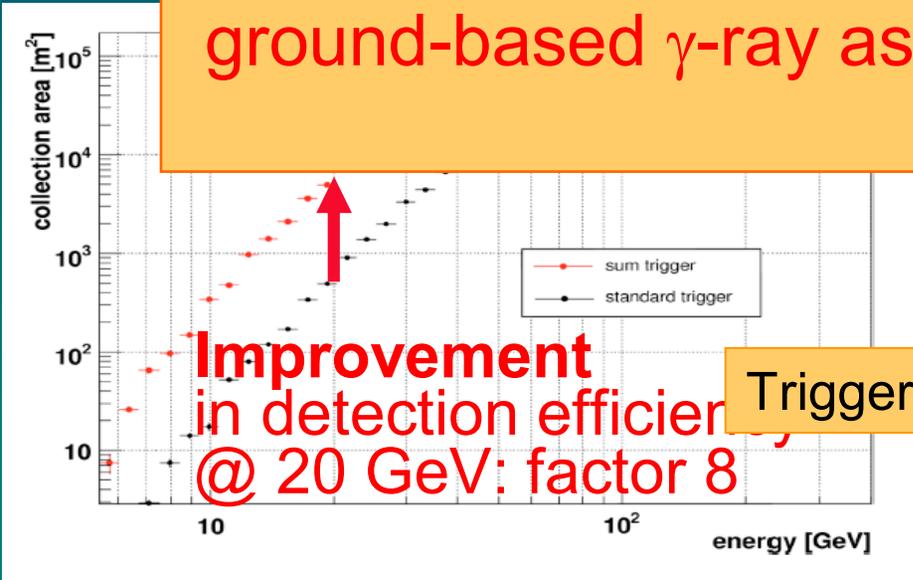

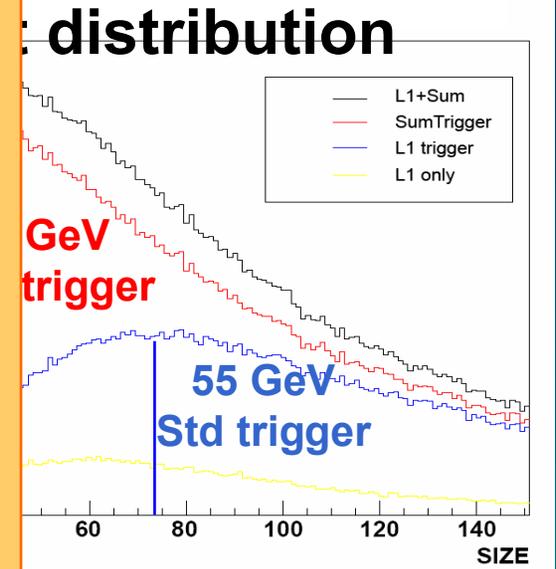

# A new trigger concept

## Improvements

- Size
- lower
- High
- Sum
- in pa

Low trigger threshold  
of 25 GeV:  
a break-through for  
ground-based  $\gamma$ -ray astronomy

Improvement  
in detection efficiency  
@ 20 GeV: factor 8

Trigger threshold decreased in a factor ~2

# Detection of the Crab pulsar above 25 GeV

MAGIC

Observations with new trigger

- Oct.07 to Feb.08: 22.3 h

Clear detection:  $6.4 \sigma$

Pulses in phase with EGRET

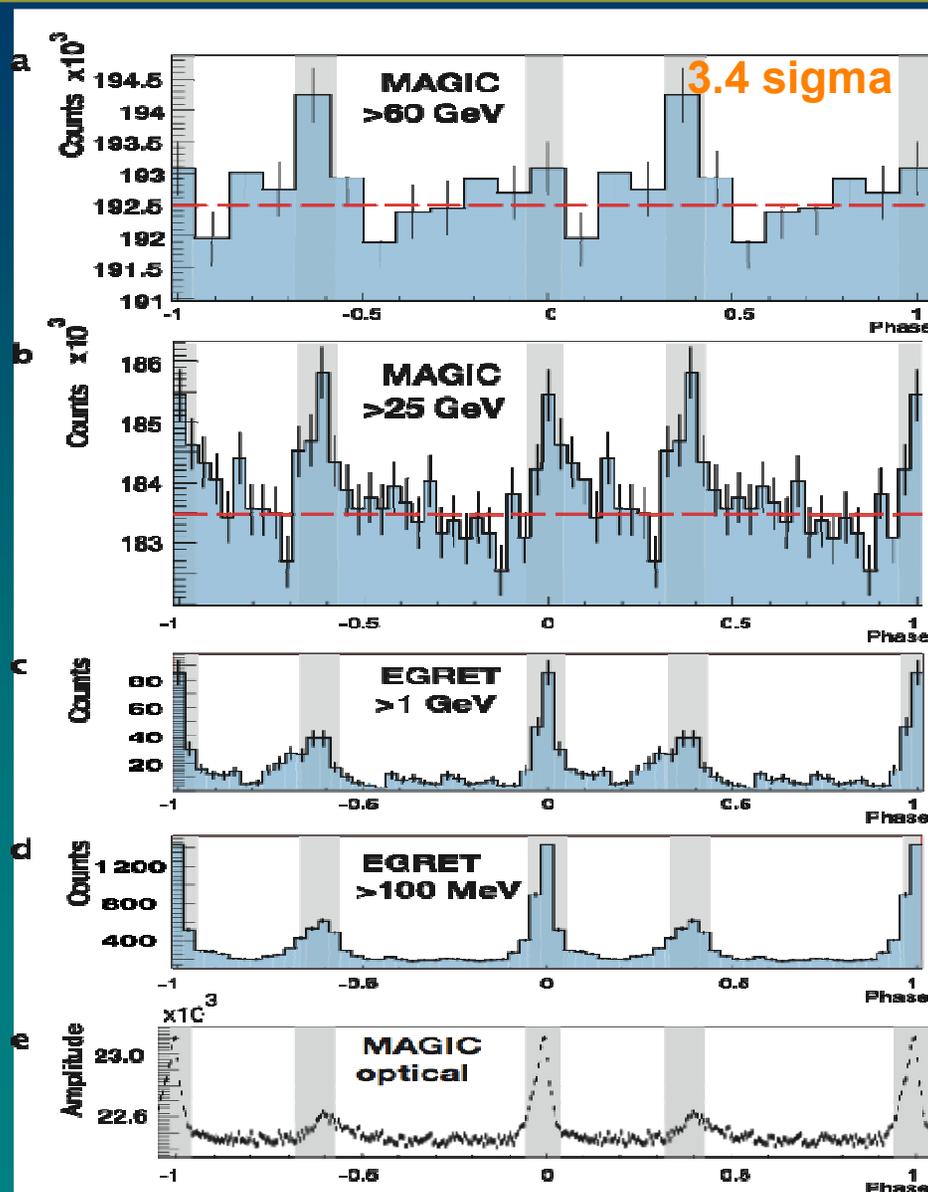

P1 clearly visible  
at 25 GeV

→ *First Surprise*

Pulsed emission  
still visible > 60  
GeV !

*P2 became  
dominant*

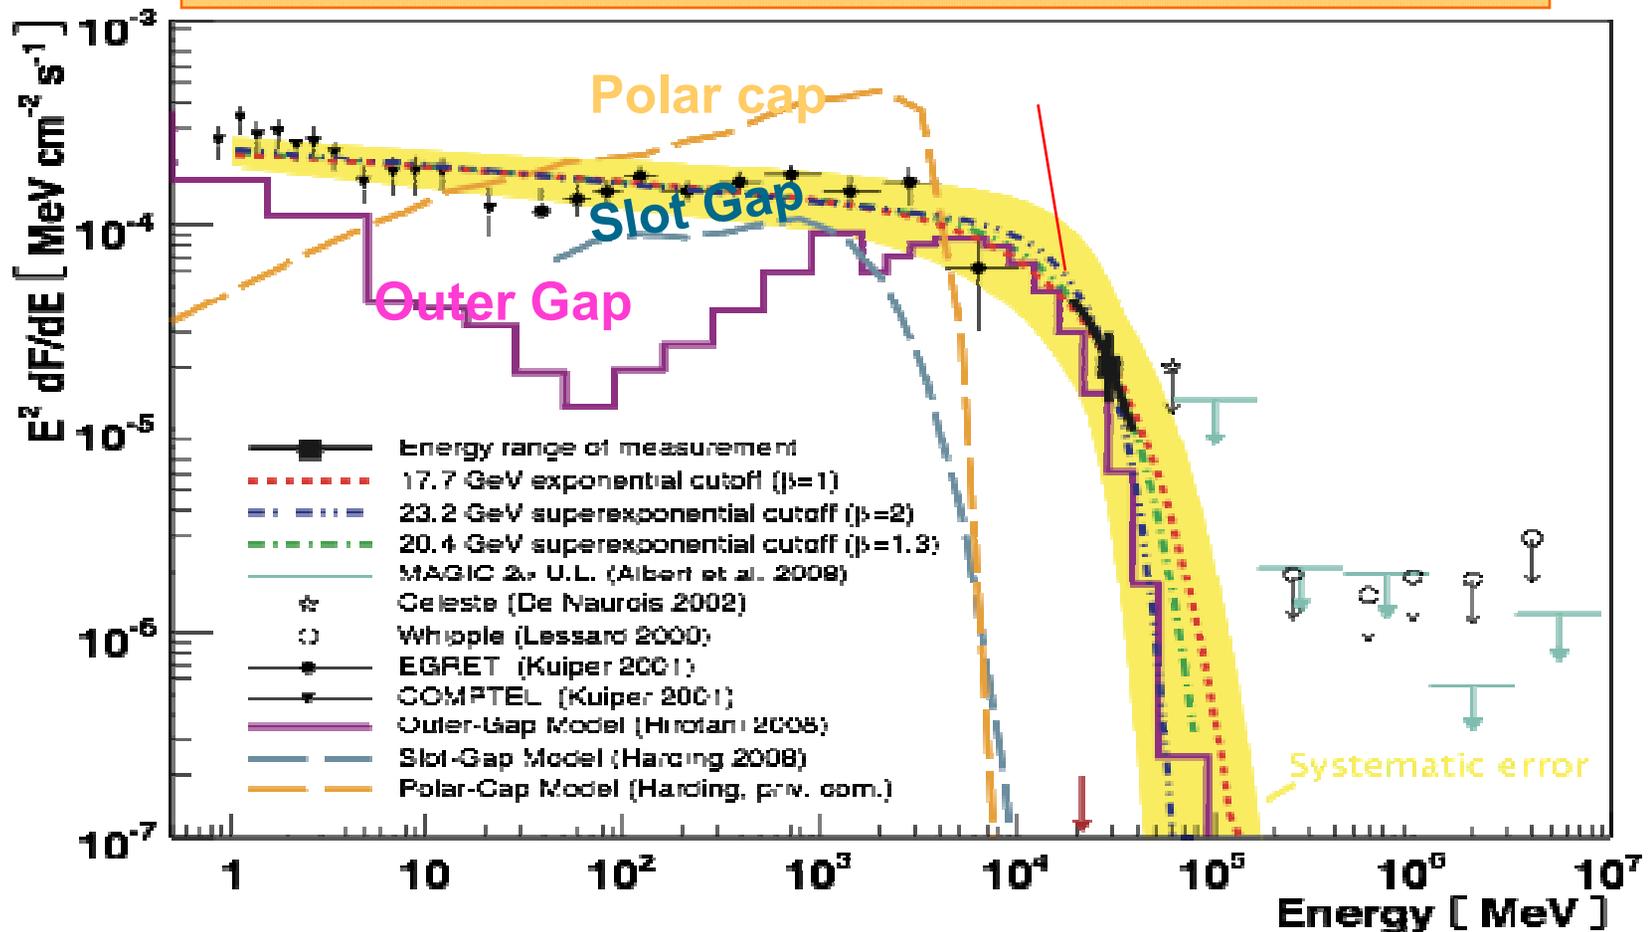

Scineghe 09, Assisi

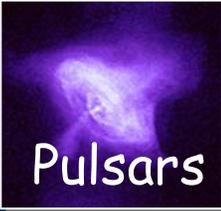

# Total spectrum & cutoff

$E_0 = 17.7 \pm 2.8_{\text{stat}} \pm 5.0_{\text{syst}}$  GeV for  $\beta = 1$  (exponential)  
 $E_0 = 23.2 \pm 2.9_{\text{stat}} \pm 6.6_{\text{syst}}$  GeV for  $\beta = 2$  (super-exponential)

# Relatively high cutoff >20 GeV ! Comparison with pulsar models

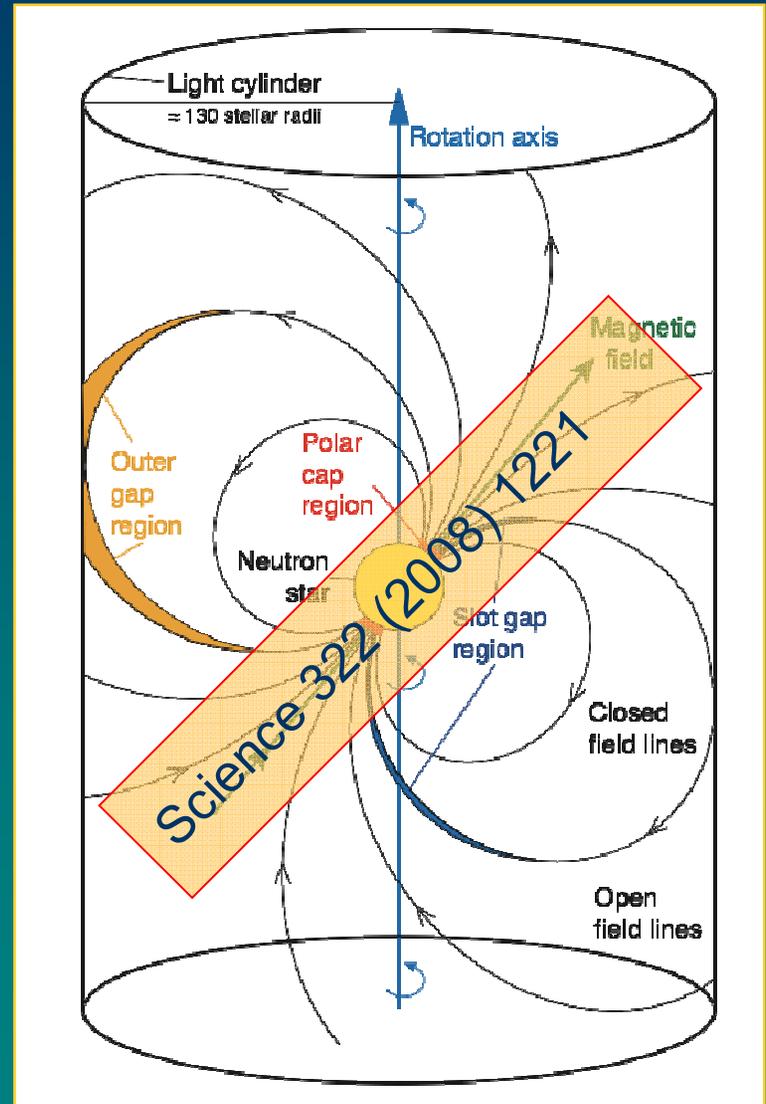

- Our superexponential cutoff:  
**23.2 GeV ± 2.9<sub>stat</sub> GeV ± 6.6<sub>syst</sub> GeV**
- We can calculate the absorption of gamma-rays in the magnetic field

$$\epsilon_{\max} \approx 0.4 \sqrt{P \frac{r}{R_0}} \max \left\{ 1, \frac{0.1 B_{\text{crit}}}{B_0} \left( \frac{r}{R_0} \right)^3 \right\} \text{ GeV}$$

Baring et al., 2001

- From which we can put a lower limit on the distance of the emitting region:  
**6.2 ± 0.2<sub>stat</sub> ± 0.4<sub>syst</sub> neutron star radii**
- **The high location of the emission region excludes the classical polar cap model (emission distance < 1 stellar radius) and challenges the slot gap model**

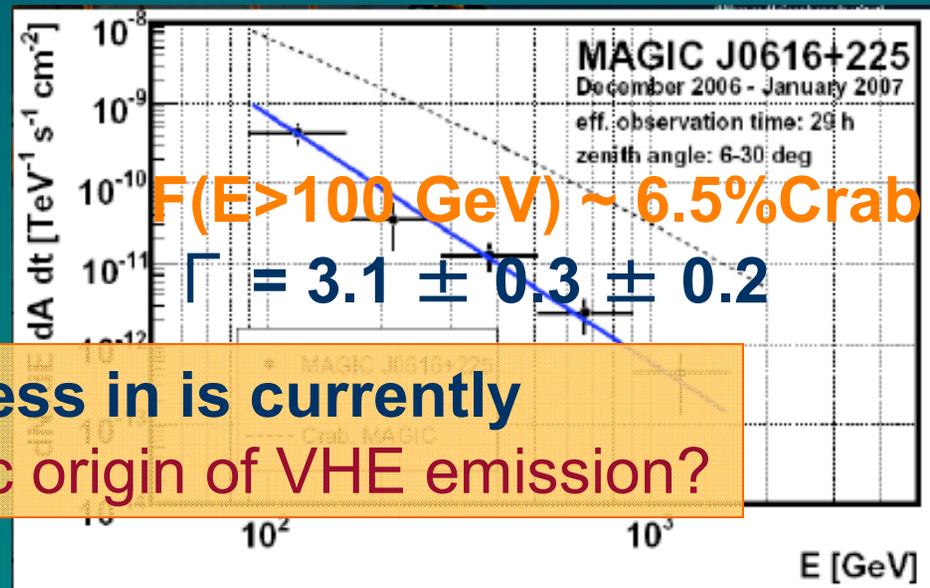

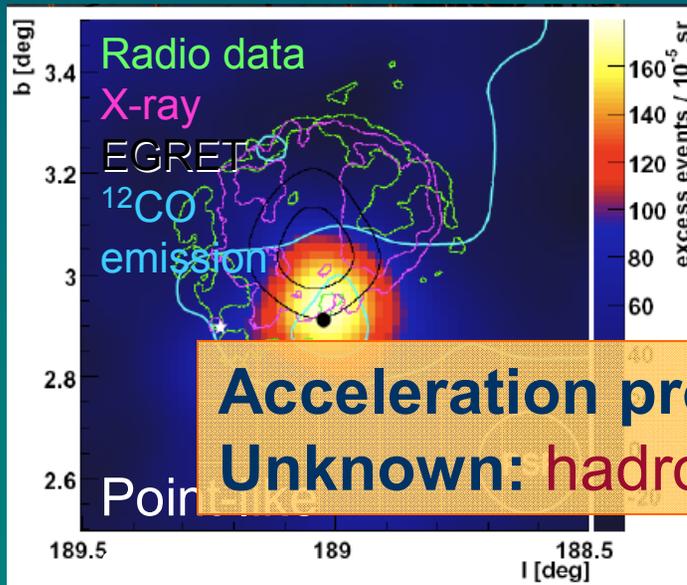

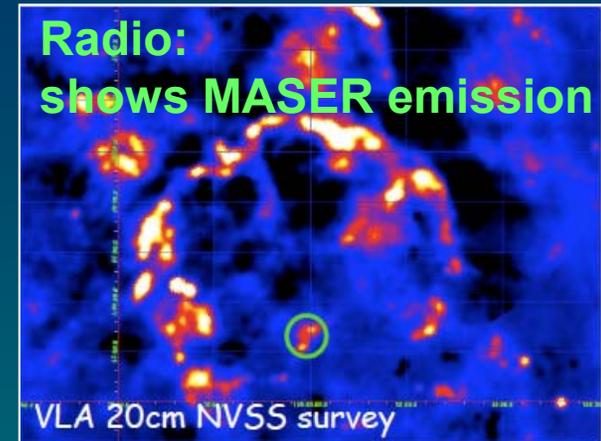

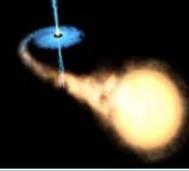

# SNR IC 443 (MAGIC J0616+225)

- Asymmetric shell-type SNR, 45' diameter (distance ~1.5 kpc)
  - Unidentified EGRET source inside
  - Only upper limits in VHE  $\gamma$ -rays
- Discovered by MAGIC in 2007 (recently confirmed by Veritas)

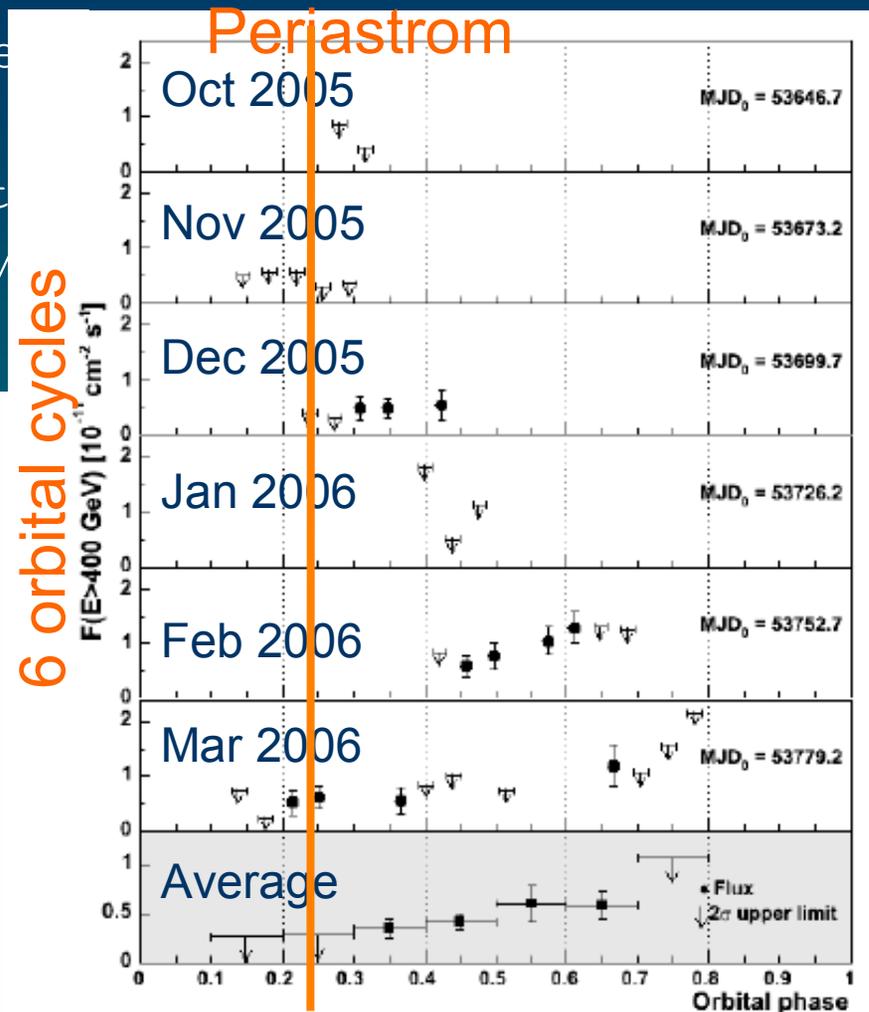

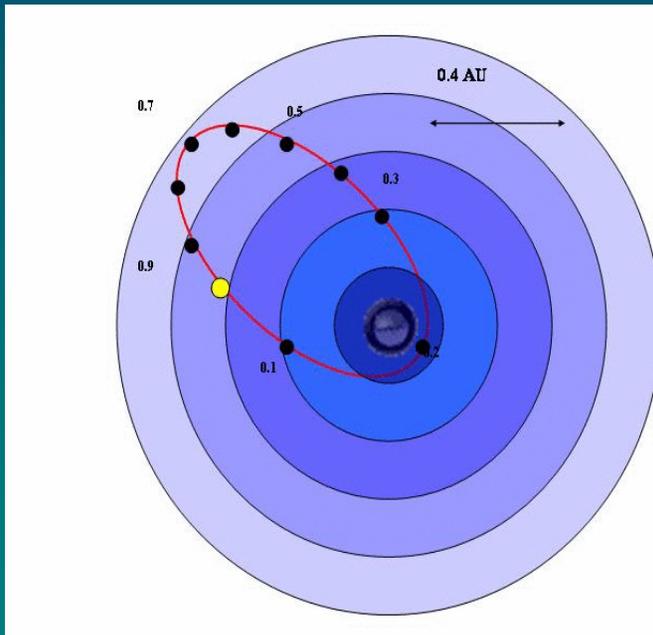

**Acceleration process in is currently Unknown: hadronic origin of VHE emission?**

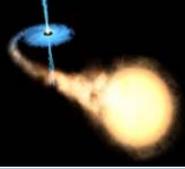

# LSI+61 303

- High mass x-ray binary system
  - Be star (18  $M_{\odot}$ ) &
  - Unknown compact object: neutron star or black hole
- Discovered by MAGIC in 2005/2006
- Visible only at some orbital phases

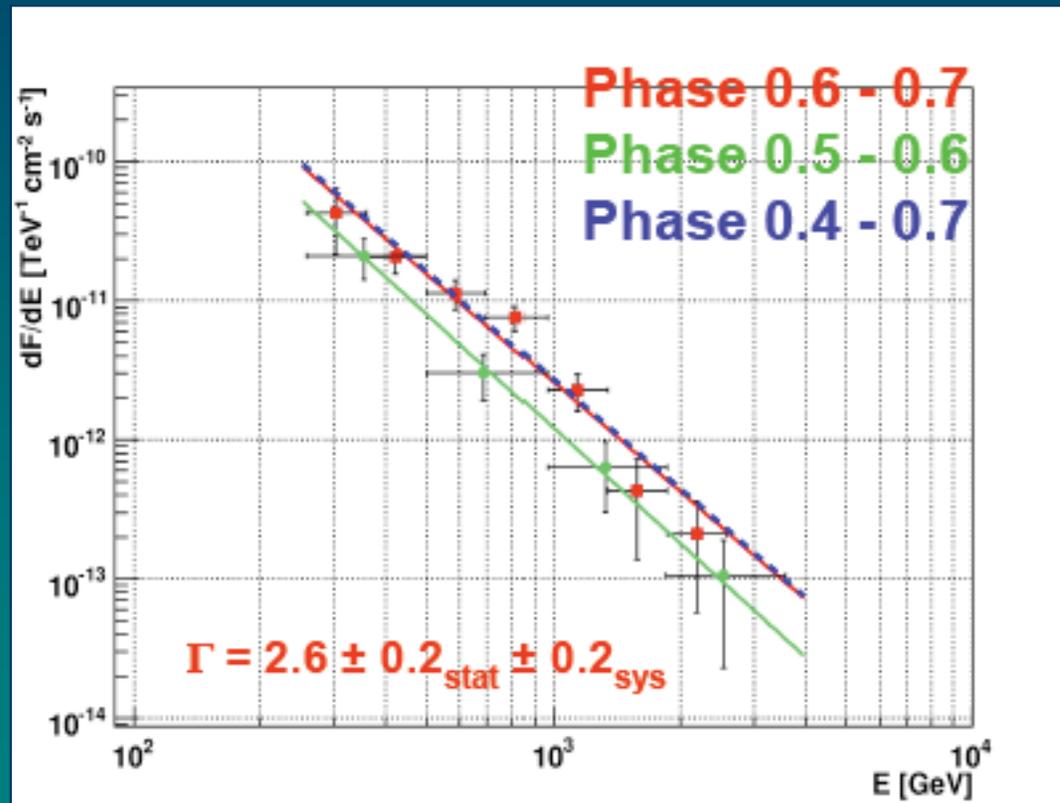

First time a periodically variable VHE emitter was seen

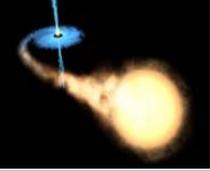

# LSI+61 303: Spectrum

Spectral index remains during different phases, even if flux changes by factor of 3

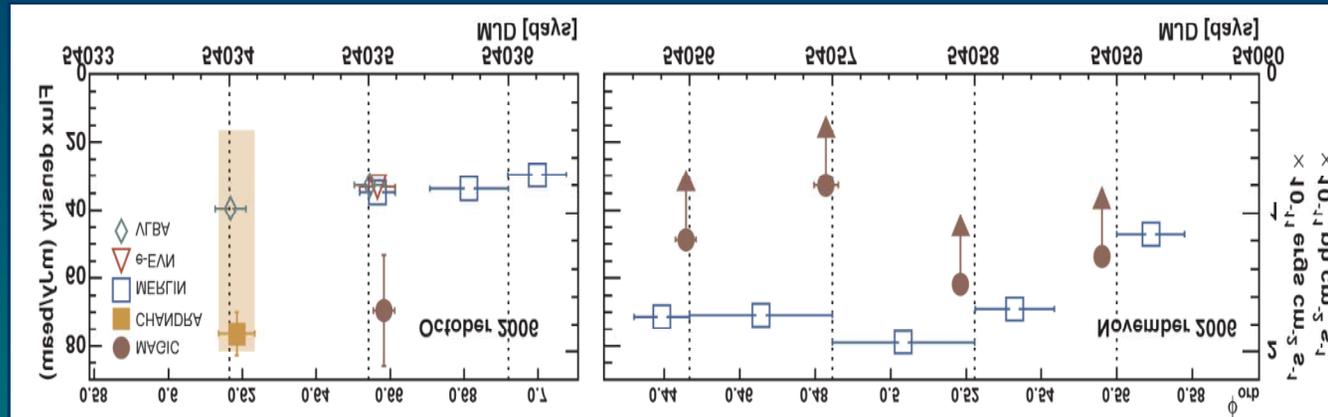

# LSI+63 303: MW campaigns

## Radio/VHE?

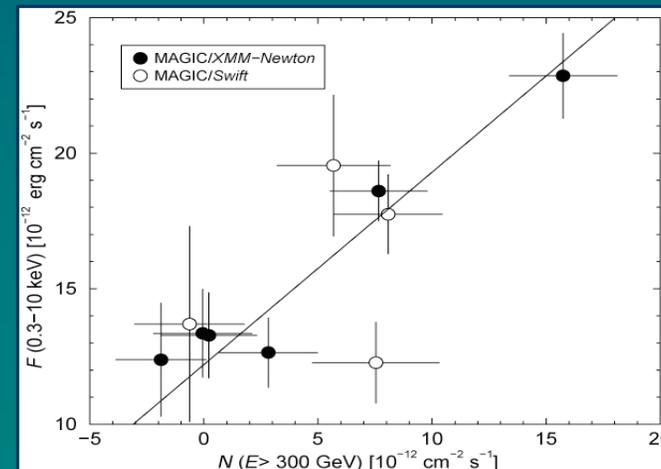

- MW campaign Oct/Nov 06 in Radio, X-rays & VHE

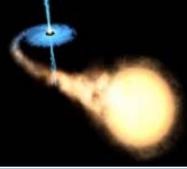

No direct correlation between radio/VHE

## X-ray/VHE?

- New MW campaign in 2007 with XMM, Newton and Swift
  - Simultaneous data show evidence for X-ray/VHE correlation ( $r=0.81$ )

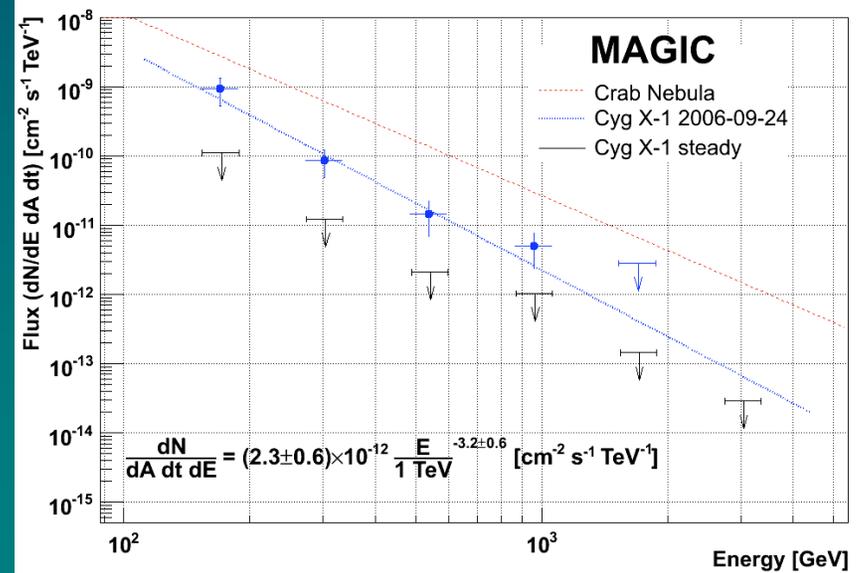

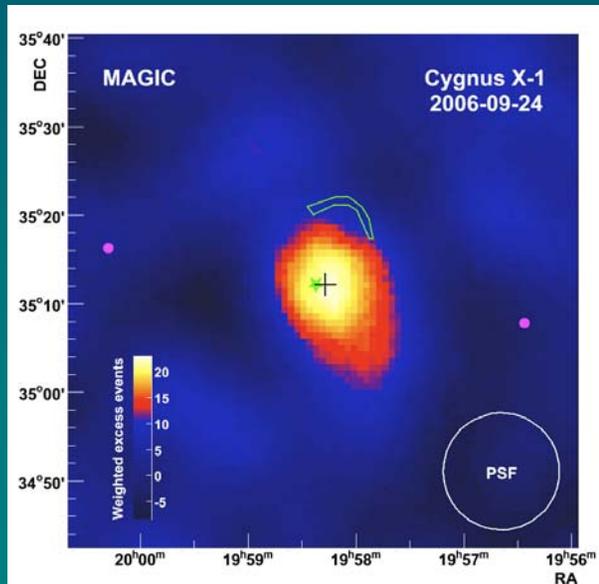

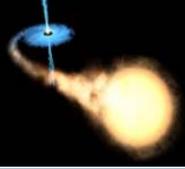

# Cygnus X-1

- One of the brightest X-ray sources in the sky
  - BH turning around an O-type star
- Observed 40h in 2006 with MAGIC in 26 nights
  - No steady  $\gamma$ -ray signal: U.L. below  $\sim 1\%$  Crab flux
  - Detected a flare on 24<sup>th</sup> Sept. 2006 at  $4.1\sigma$  (post trial)

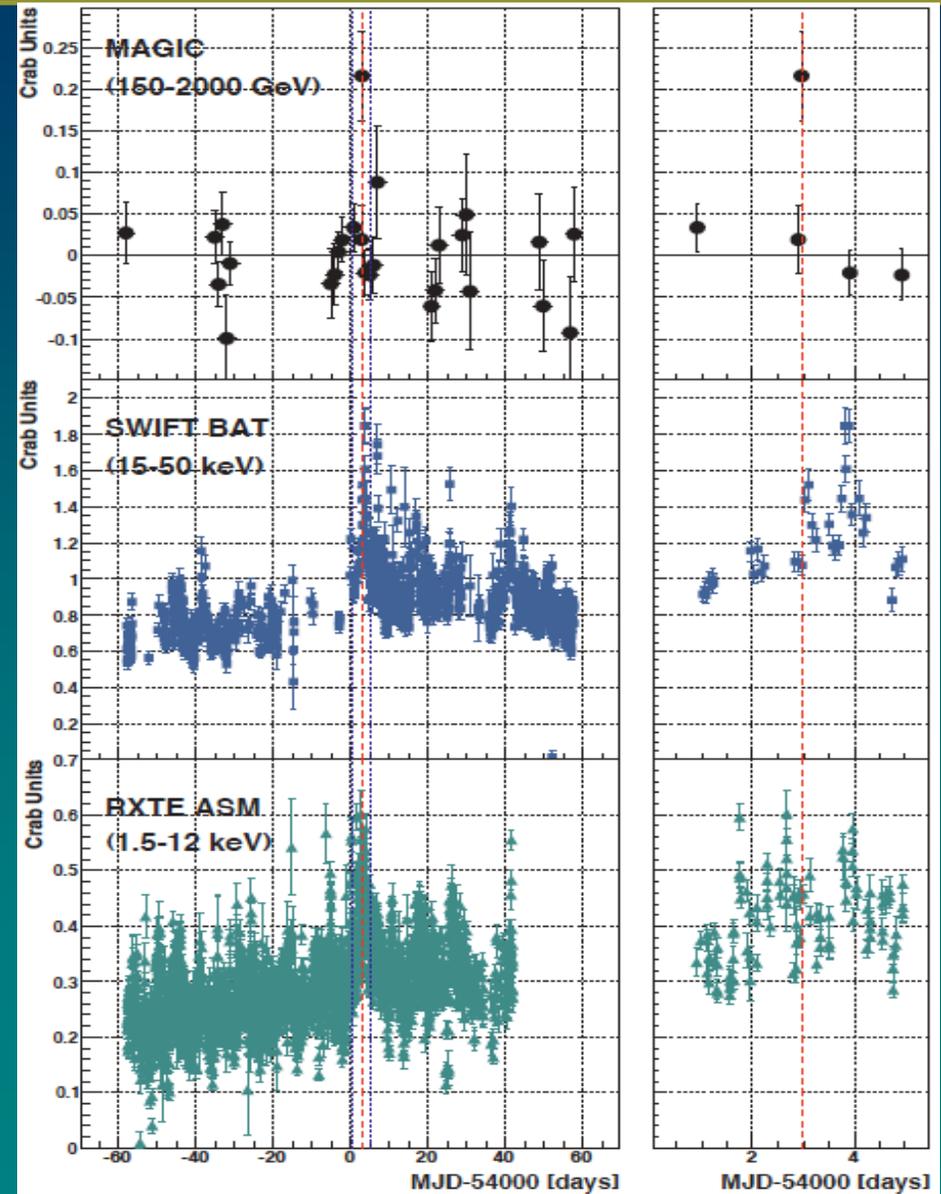

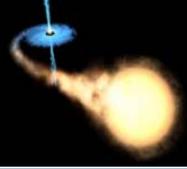

# Cygnus X-1

- VHE flare coincident with X-ray flares seen by Swift/BAT, RXTE/ASM and Integral
- TeV excess observed at rising edge of first hard X-ray peak
- Hard X-rays and VHE  $\gamma$ -rays could be produced at different regions of the jet  
 → shift between TeV- and X-ray peak

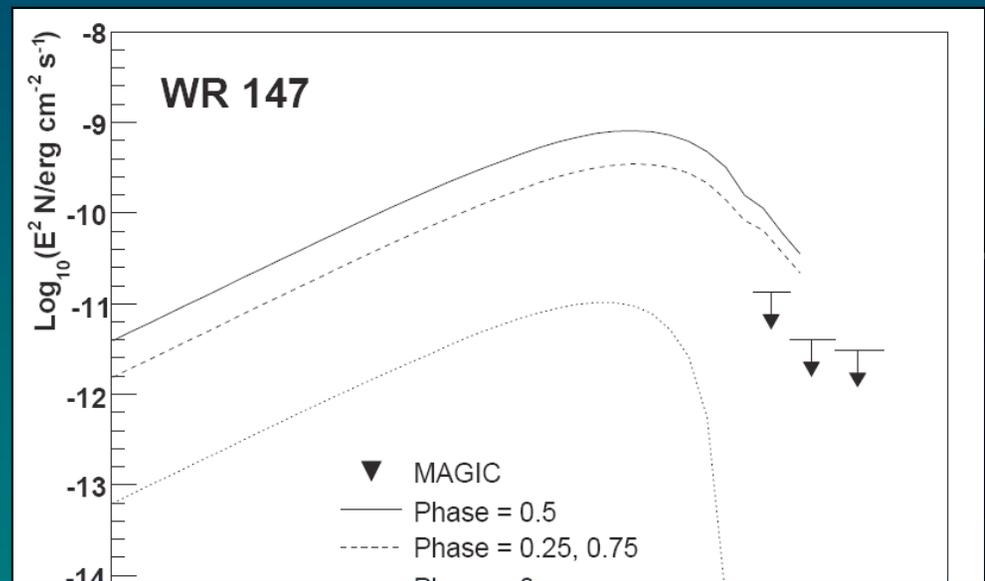

# Wolf-Rayet binary systems

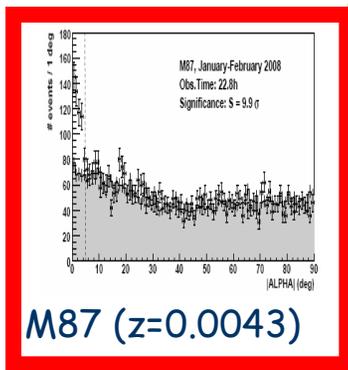

- Binary systems containing a WR star :
  - colliding winds (up to 5000km/s) could produce  $\gamma$ -rays via leptonic or hadronic processes (e.g. Reimer et al. 2006)
- MAGIC observed two WR binary systems:
  - **WR146**: WC6+O8 colliding wind binary system in the field of view of TeV J2032+4130; combined observation, T=30h
  - **WR147**: WN8(h) plus a

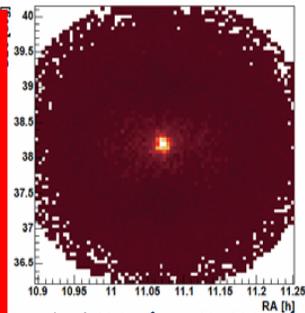

Reimer's model for WR147 assumes parameters still unknown → Model can't be rule out, but the phase can be constrained (period is 1500yrs!)

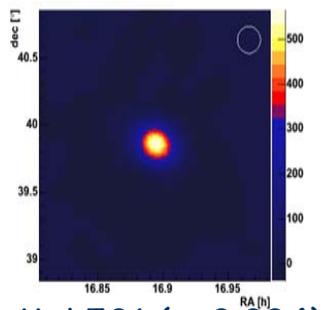

# Highlights in MAGIC extragalactic observations

1ES1011 ( $z=0.212$ )

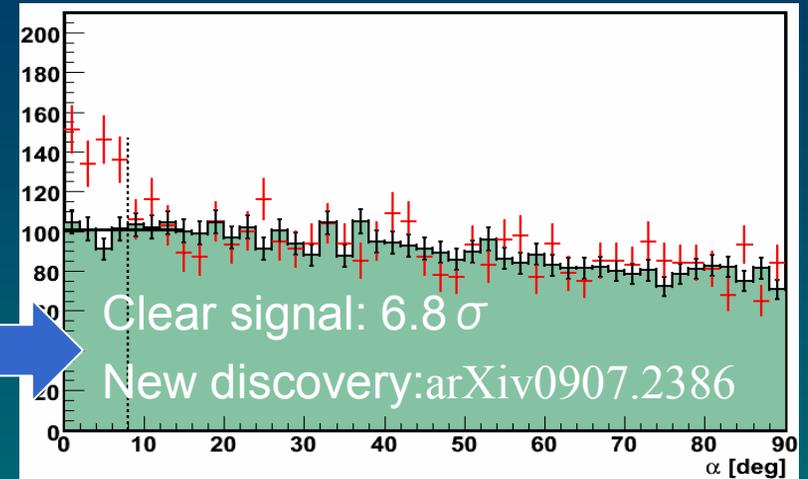

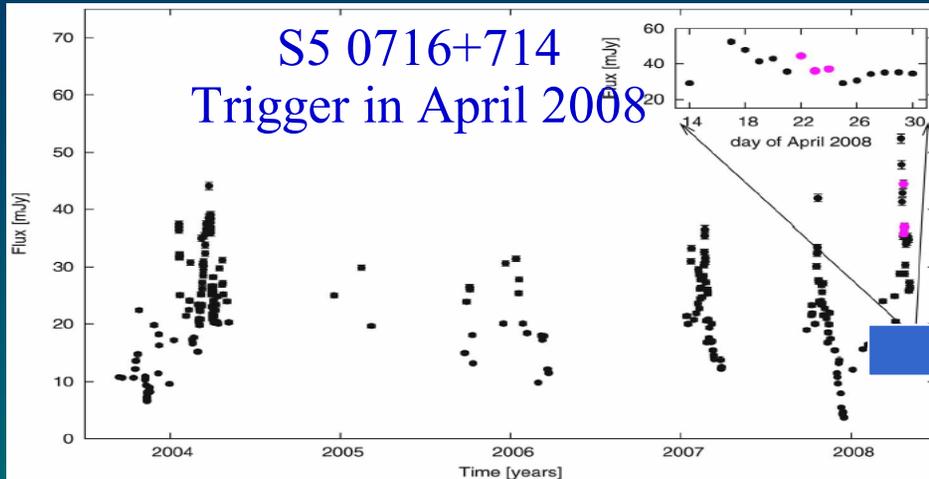

# Optical triggers → new VHE sources

- Regular optical monitoring of candidate sources by KVA telescope (close to MAGIC site)

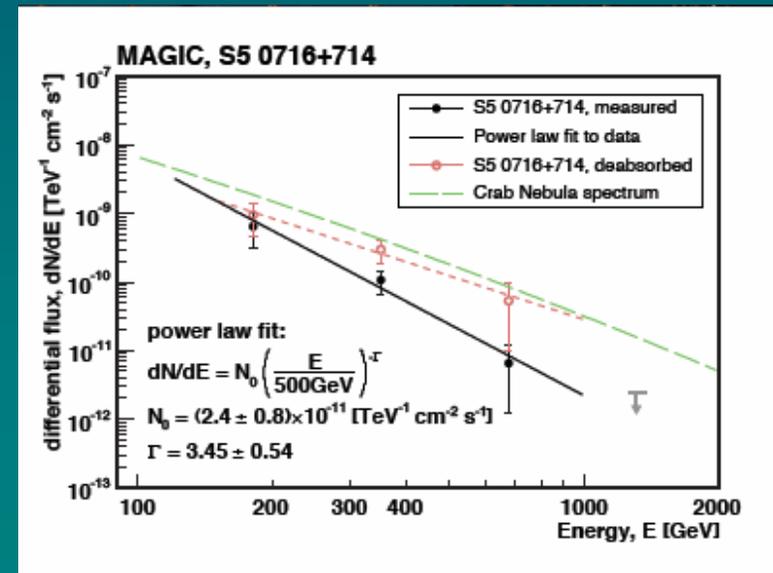

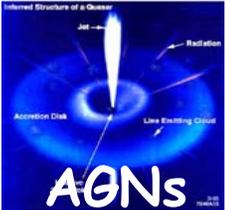

# S5 0716+714

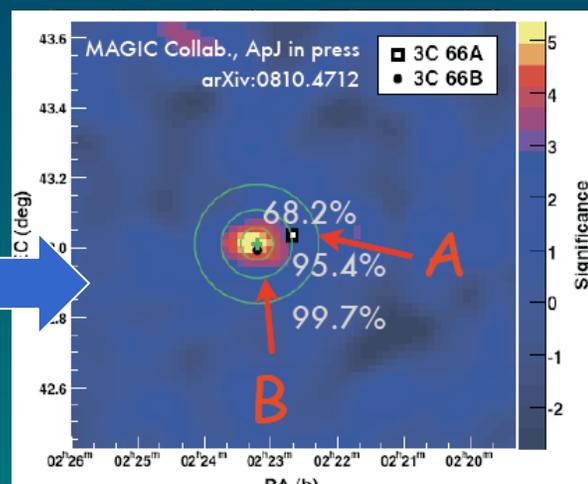

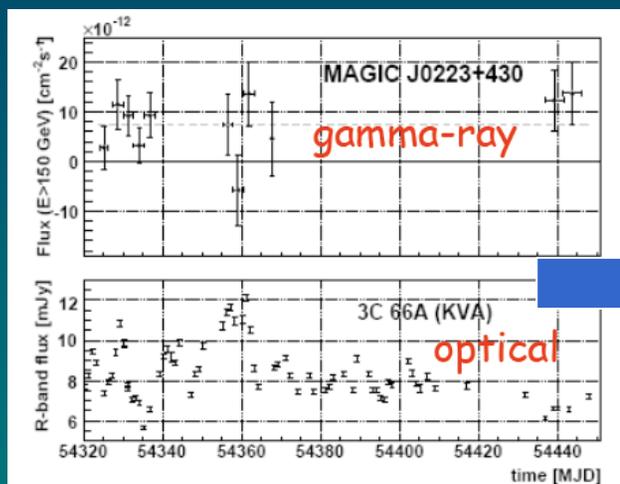

- After trigger, MAGIC observed 2.6h
- ▶ April 28: Swift reports flux about 50% larger than that observed in 2007
- ▶ Apr 29: ATel #1500, MAGIC reports  $6.8 \sigma$  discovery Apr 23-25.  $F(>400 \text{ GeV}) \approx 25\% \text{ Crab}$
- 3<sup>rd</sup> low-peaked VHE blazar after BL Lac & W comae
- Host galaxy detected:  $Z=0.31 \pm 0.08$   
2<sup>nd</sup> farthest VHE emitter

# Observations in the vicinity of 3C 66A

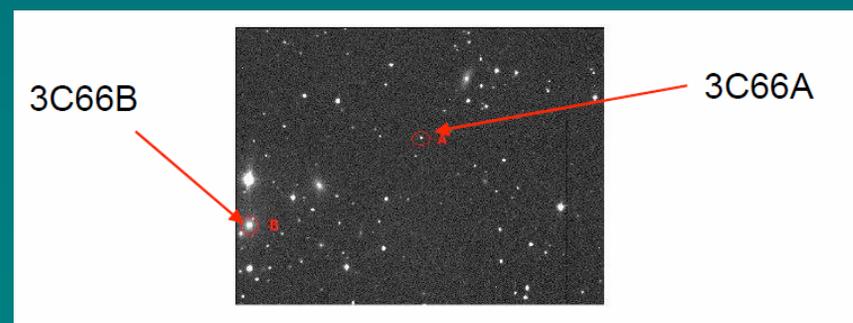

- Optical outburst in August 2007 triggered MAGIC observation:
  - from August to December, a total of 54.2 h
- Detection at  $5.4 \sigma$ ,  $F(E>150 \text{ GeV}) = 2.2\% \text{ Crab}$

3C 66B is the most likely identification:  
3C 66A excluded with 85% probability

A or B?

- **3C 66A/B: just separated 6' in the sky**
  - 3C 66A blazar with uncertain redshift,  $z=0.32-0.44$
  - 3C 66B large FR-I radio galaxy, similar to M87,  $z=0.0215$

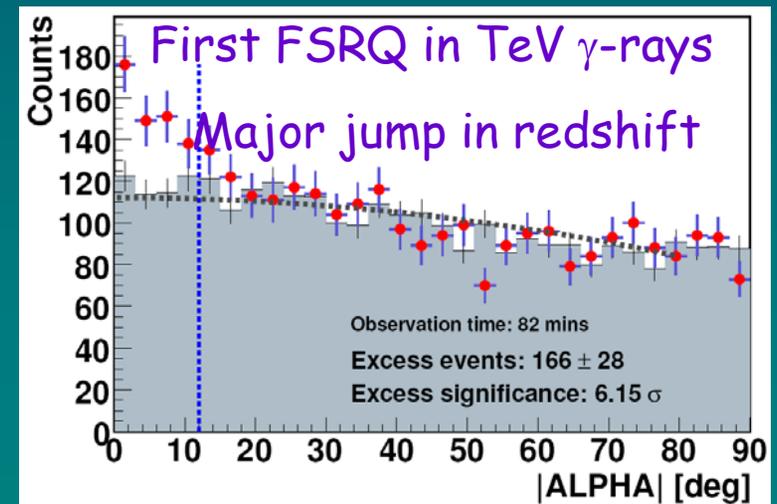

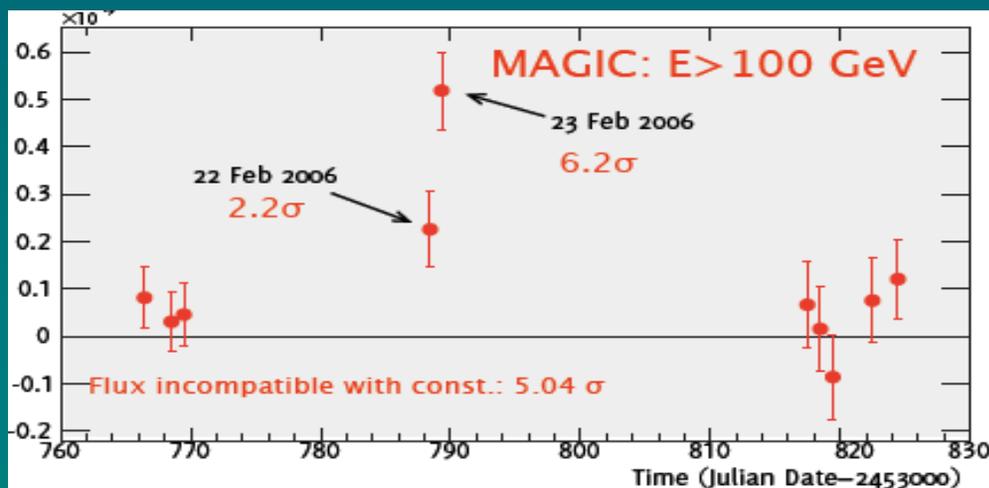

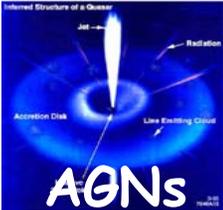

# The distant quasar 3C 279

- Flat spectrum radio quasar ( $z=0.54$ )
- Very bright and strongly variable
  - Brightest EGRET AGN
  - Gamma-ray flares in 1991 and 1996. Fast time variation ( $\sim 6$  hr in 1996 flare)
- MAGIC observations
  - 10 h between Jan.-April 2006
  - clear detection on 23<sup>rd</sup> Feb. at  $6.2\sigma$

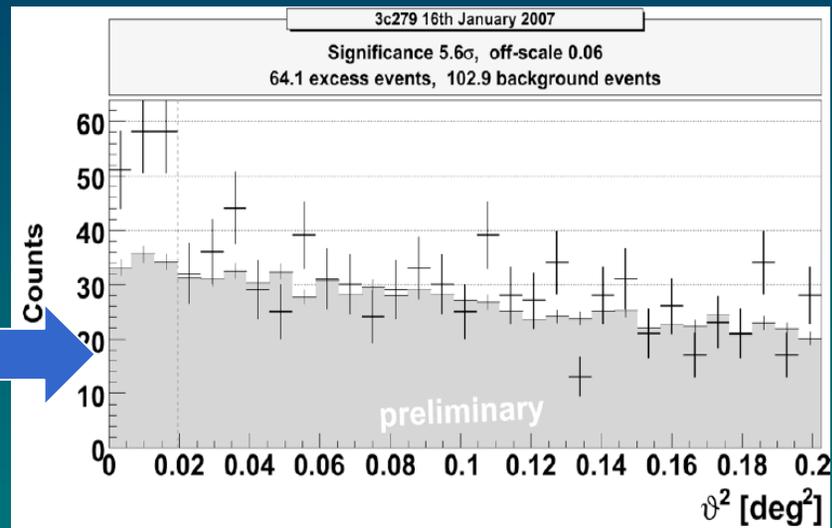

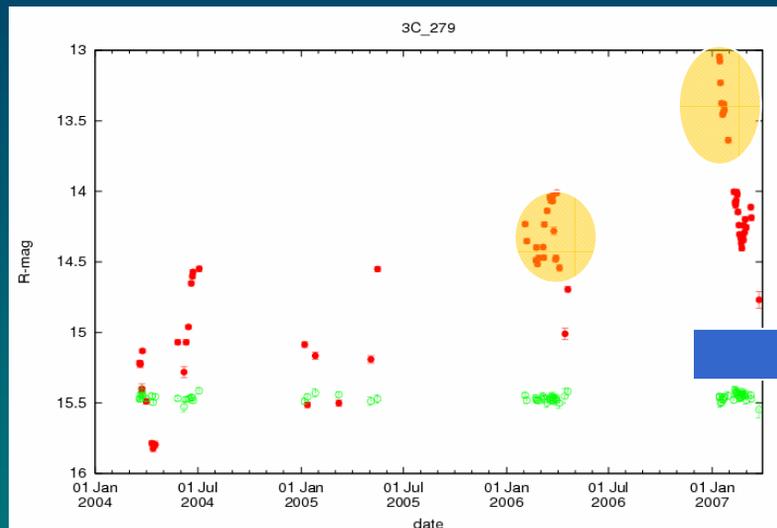

# The distant quasar 3C 279

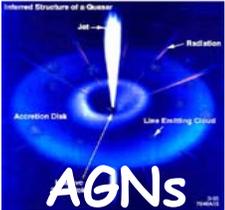

- New observations after optical outburst in Jan. 2007  
→ New flare detected

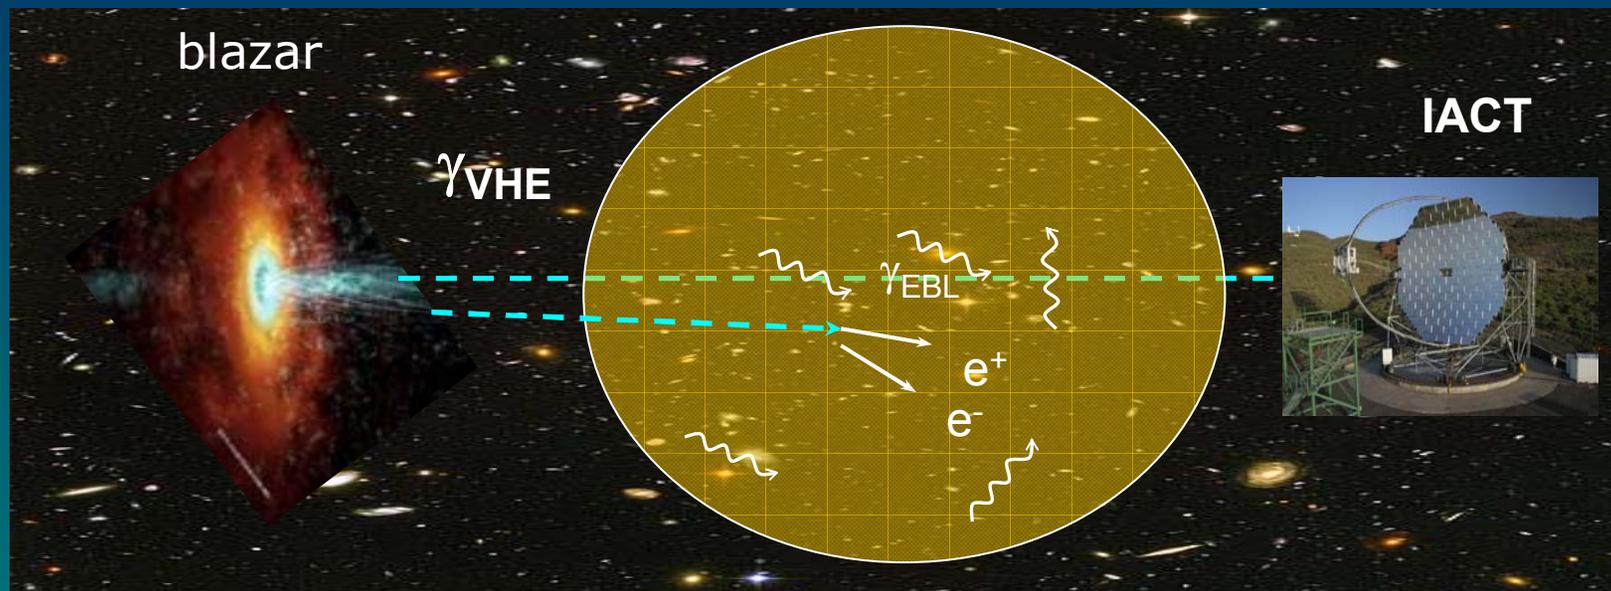

Most distant object ever detected at VH,E during two flares  
(Feb. 2006 and Jan. 2007)

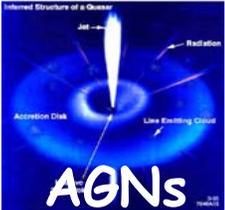

Emission harder than expected -> constrains the EBL, universe more transparent to  $\gamma$ -rays than expected

# Implications on Extragalactic Background Light

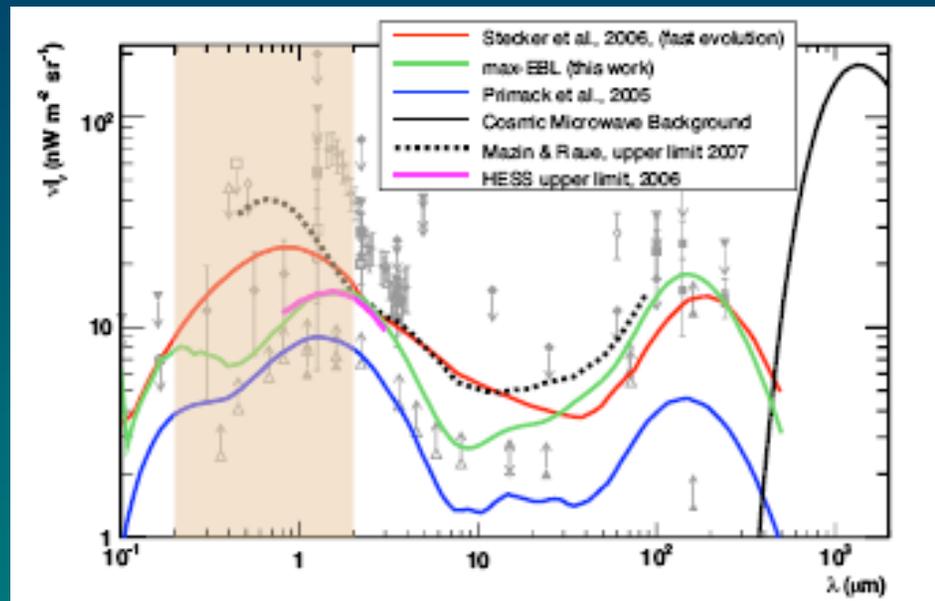

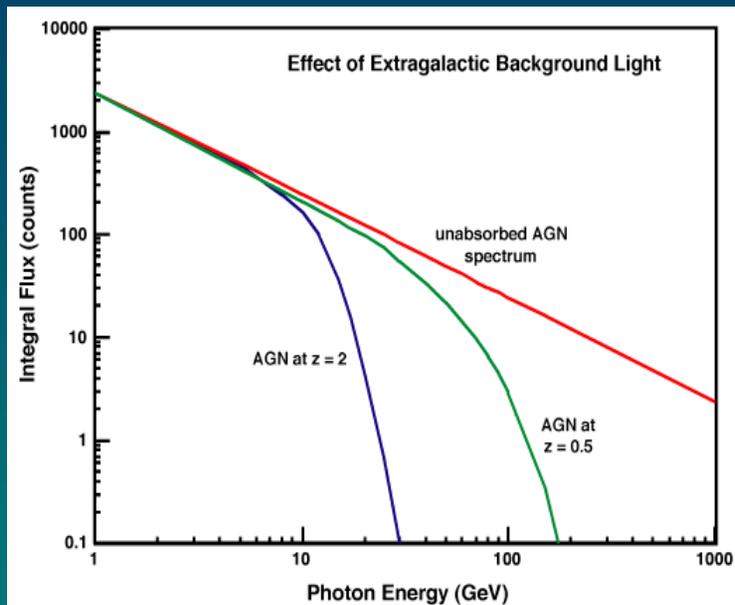

- $\gamma$ -rays from the source interact with the EBL in their way to the Earth, producing  $e^{\pm}$  pair.
- For  $\gamma$ -rays, relevant background component is optical/infrared (EBL)
- different models for EBL: minimum density given by cosmology/star formation

# Implications on Extragalactic Background Light

## AGNs & EBL

- Measured spectrum affected by attenuation in the EBL

- Measurement of spectral features permits to constrain EBL models:
  - 3c 279 Power law  $\Gamma = -4.11 \pm 0.68 \rightarrow$  Spectrum sensitive to 0.2 to 2

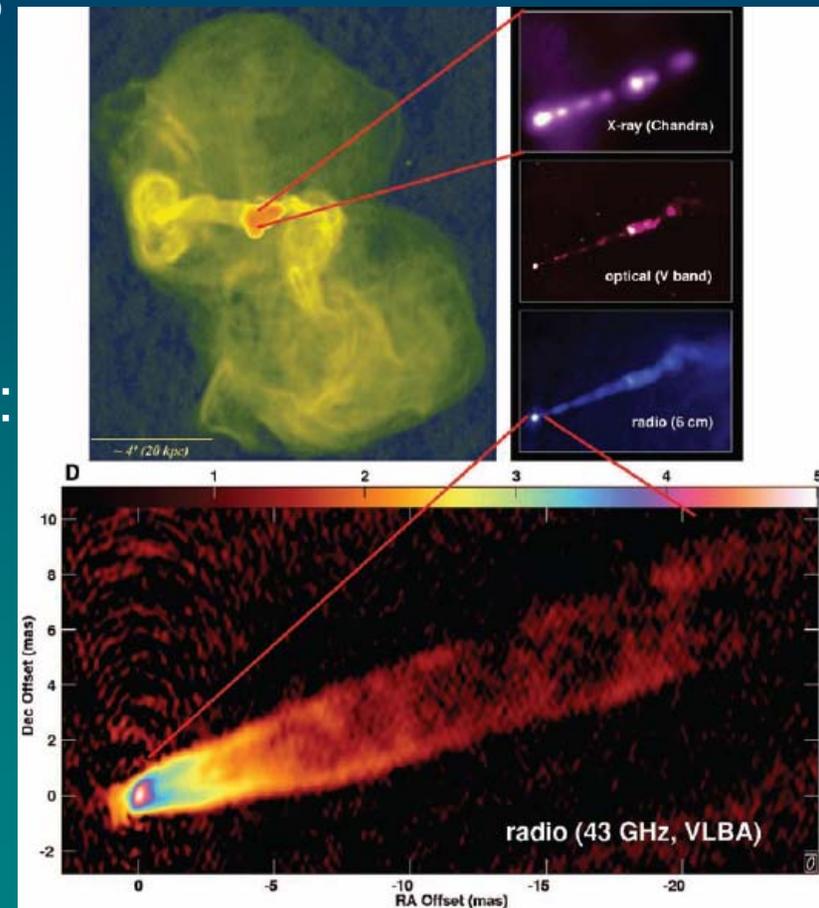

The Universe appears more transparent at cosmological distances than believed

Upper limit close to lower limit from galaxy count

# M87 giant flare

- Radio galaxy with super massive black hole  $\sim 6 \cdot 10^9 M_{\odot}$  at  $\sim 16$ Mpc
- Jet structure with knots, sometimes brighter than nucleus
- Established VHE  $\gamma$ -ray emitter: HEGRA, HESS, Veritas & MAGIC
  - Site for TeV emission (core/HST-1)?
- Source of UHECR?

# M87 giant flare

Science, 325 (2009) 444

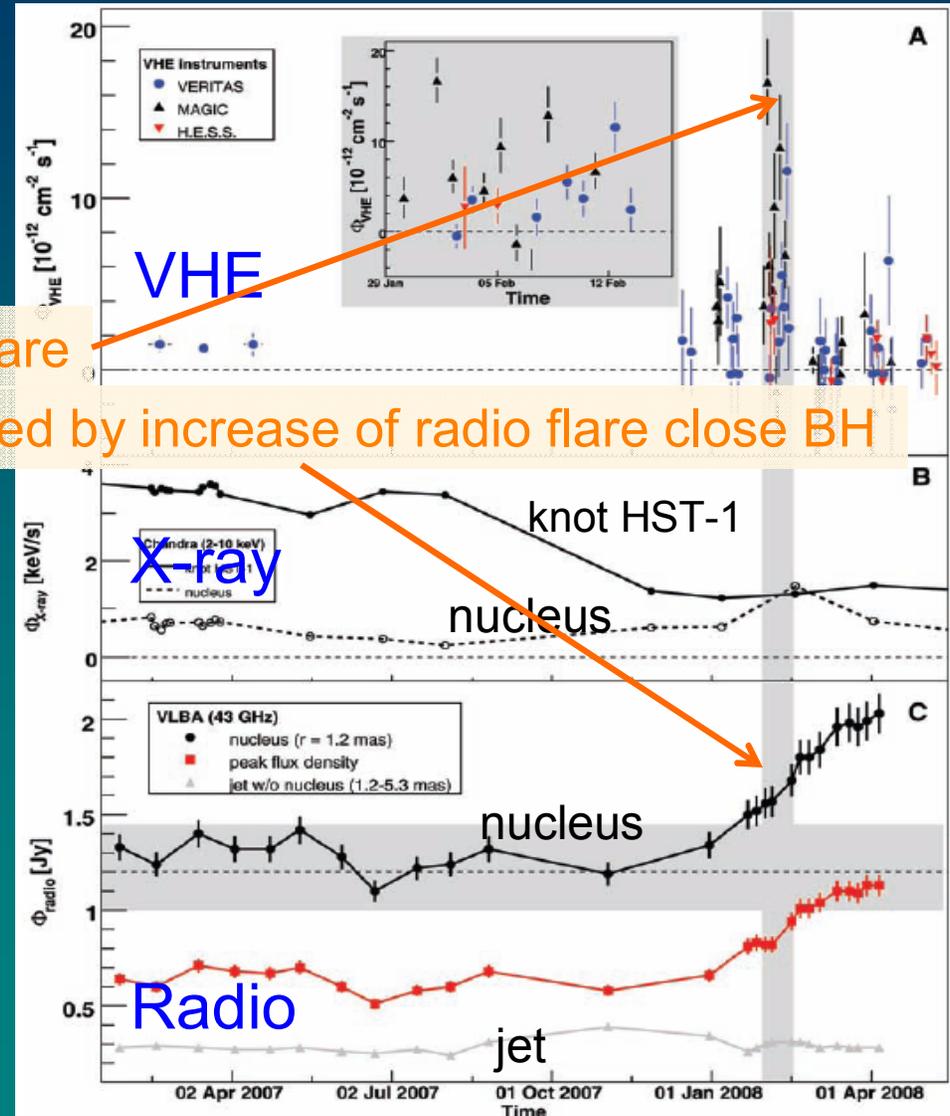

Joint paper MAGIC-VERITAS-HESS-VLBI-Chandra

## MWL campaign Jan-Feb 2008

- Triggered by MAGIC detection on 1st February flare:
  - 9.9 $\sigma$  detection; 8.0 $\sigma$  significance
  - night 1st-feb
- Discovered:
  - Fast (day-scale) variability
  - Correlated TeV flare with radio & X-ray emission from the core, while emission from HST-1 knot stayed low
- Origin of the VHE  $\gamma$ -ray emission is most likely the core of the jet

VHE flare

Followed by increase of radio flare close BH

# Indirect Dark Matter searches

MAGIC

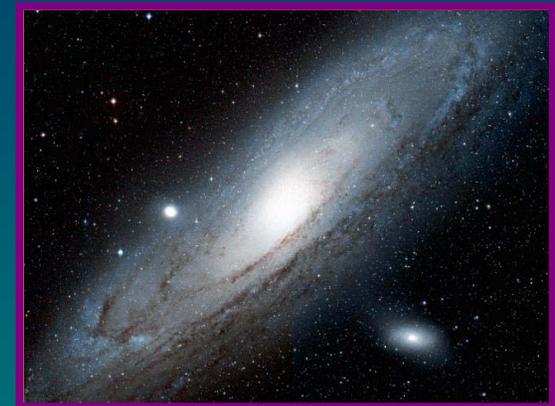

- Standard Cosmological scenario of **Cold Dark Matter**
- **Neutralino** (lightest SUSY particle) attractive candidate

$\gamma$ -flux from  $\chi$  annihilations:

$$\Phi_{\gamma}(\Omega) \propto \frac{N_{\gamma} v \sigma}{M_{\chi}^2} \int \rho_{DM}^2(l) dl(\Omega)$$

Particle phys. X Astrophysics

**CDM density:**  $\gamma$ -ray flux  $\sim \rho^2 \Rightarrow$  need region with high  $\rho$

Where to search?

- Galactic center? obscured by strong VHE source
- Other galaxies, galaxy clusters? expect other VHE
- minihalos, IMBHs, ...? don't know where they are (yet)
- spheroidal satellite dwarf galaxies ? expect to be dim but cleaner signal

# Observations of Sph. dwarf galaxies

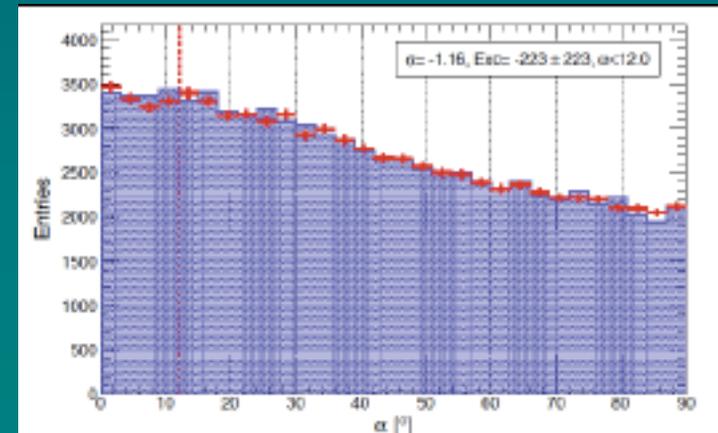

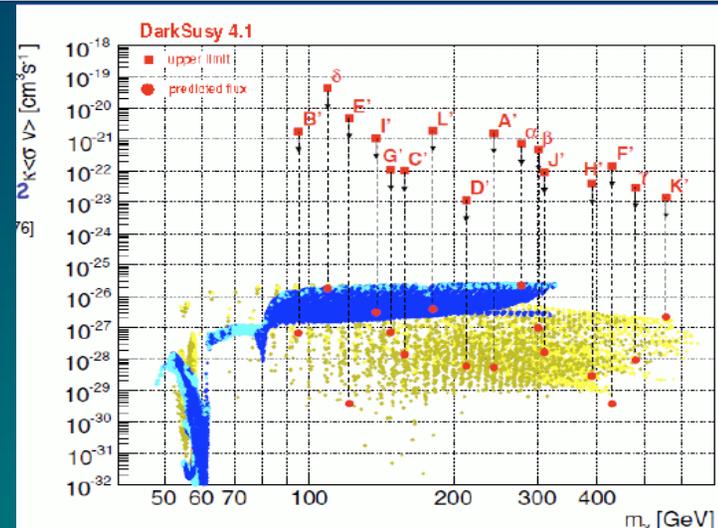

Need significant increase in sensitivity to come close to model predictions

## ■ Draco

- 8h in 2007 at large zenith angle ( $37^\circ$ )  $\Rightarrow E_{th} = 140 \text{ GeV}$
- u.l.:  $\Phi(E > 140 \text{ GeV}) \sim 10^{-11} \gamma \text{ cm}^{-2} \text{ s}^{-1}$  (assuming spectral index -1.5)
- U.l. depends on expected spectra: different for each mSUGRA model

## ■ Willman I

- 15h in 2008
- u.l.:  $\Phi(E > 100 \text{ GeV}) \sim 10^{-11} \gamma \text{ cm}^{-2} \text{ s}^{-1}$

# MAGIC goes stereo...

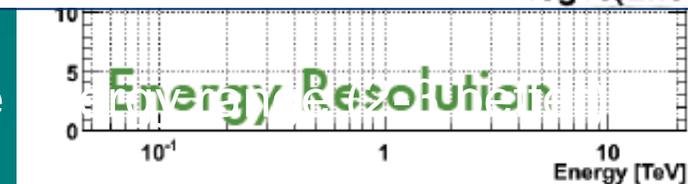

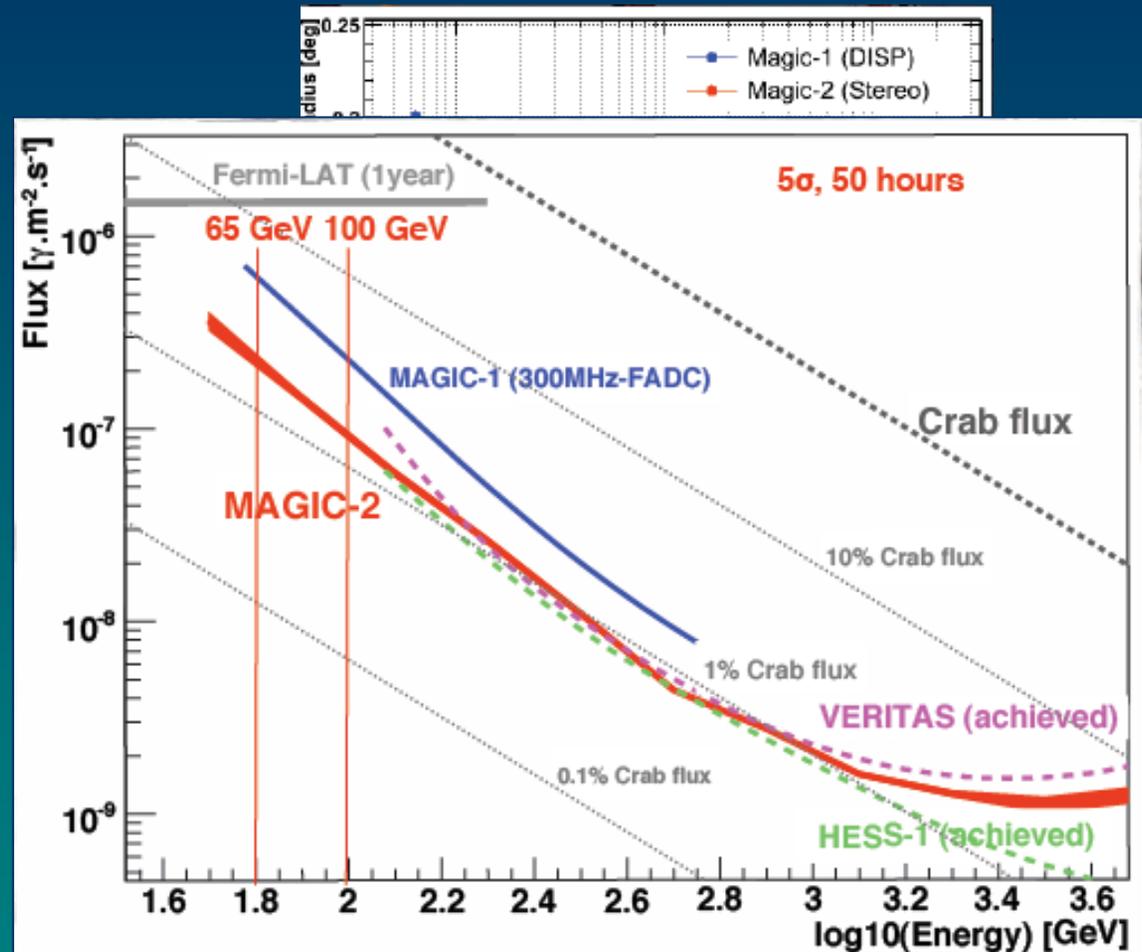

## Why stereo?

Stereoscopic provides:

- Better reconstruction of shower direction
- Additional shower param.:
  - Impact parameter
  - Shower maximum
- Eliminate ambiguity on shower arrival direction

## This means:

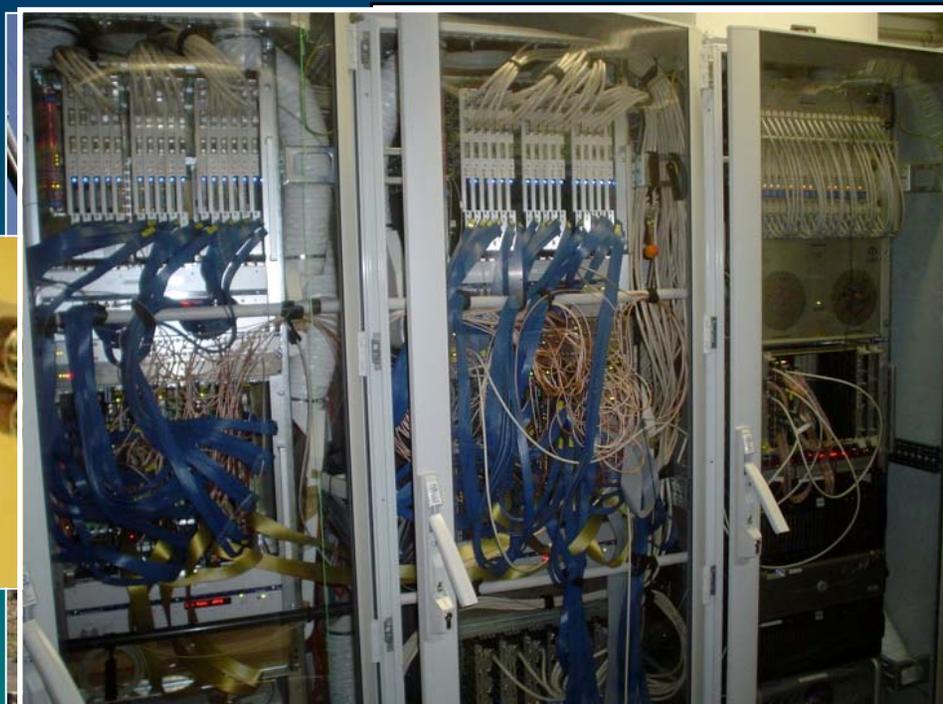

- Better hadron rejection
- Better angular resolution
- Better energy resolution
- Enhance the sensitivity over the whole

# MAGIC-II not just a clone

- Improved 1m<sup>2</sup> mirrors:
  - bigger, lighter
  - 2 technologies: Al, glass
- Improved camera:
  - High efficiency PMTS
    - ❖ 1039 x 0.1° pixels
  - Modular Design
    - ❖ Cluster of 7 pixels
    - ❖ Easy replacement
  - Total FOV = 3.5°
- Improved readout:
  - Uses DominoRing sampler
- Increased trigger area
  - Improved sensitivity for: sky scans, extended sources

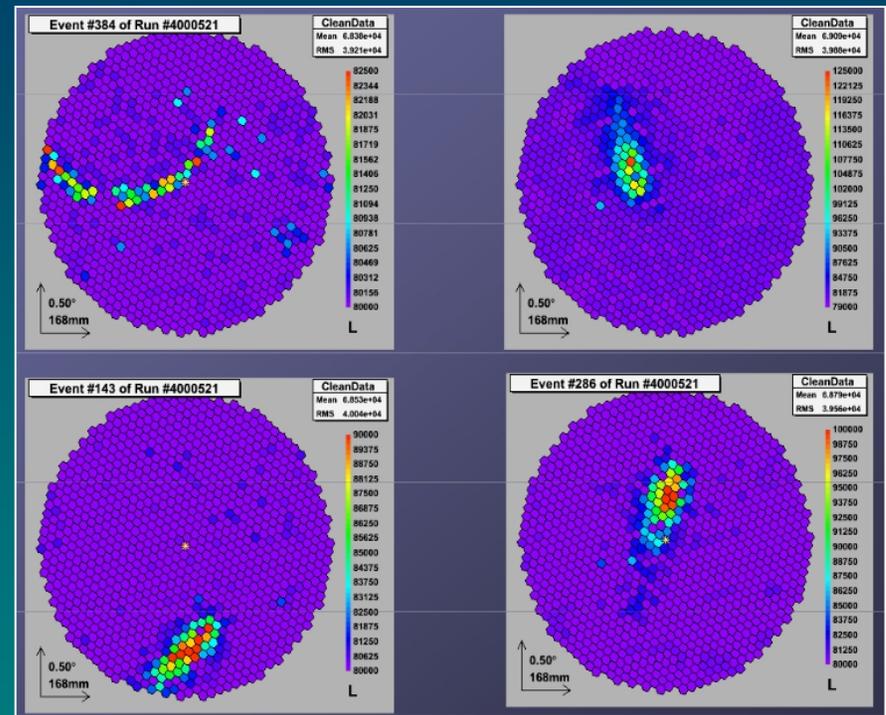

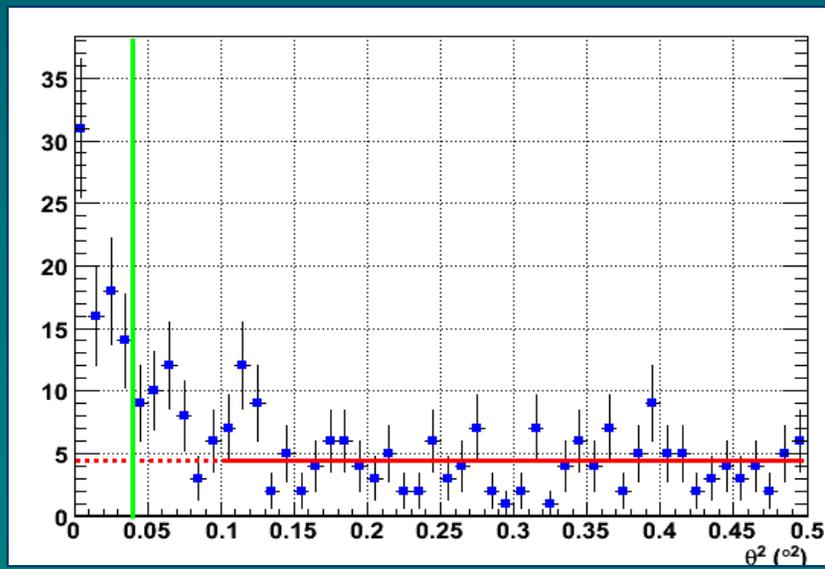

Installed December 2008

# MAGIC-II already running!

- First images & inauguration in April 2009
- First stereo events in June
- Since September all data taken with both telescopes

# Conclusions

---

- MAGIC is producing high quality physics after 4 observation cycles:
  - last year 15 articles published, 2 in Science
- We have discovered new sources (and new populations)
  - 4 new galactic sources + 8 extragalactic, and studied many others in high detail
- Important contributions to the understanding of pulsars, AGN, EBL...
- MAGIC-II just started regular operations

and astronomy into  
the modern field of  
astroparticle  
physics"*

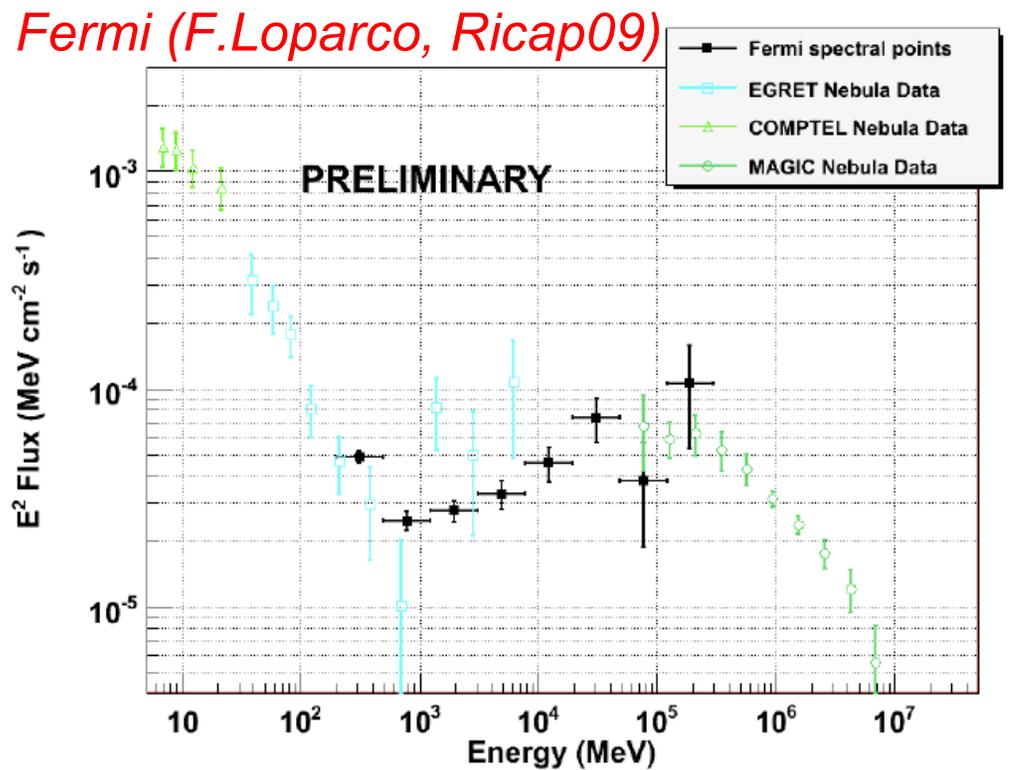

**BACKUP**

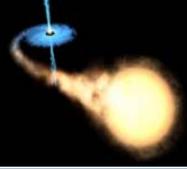

# Best studied: the Crab Nebula

- Crab Nebula spectrum measured with high precision **between 60 GeV and 9 TeV**
  - Good agreement with other other CTs above 400 GeV
- First determination of the IC-peak:  
 $E = (77 \pm 35) \text{ GeV}$
- Spectrum well described within SSC model

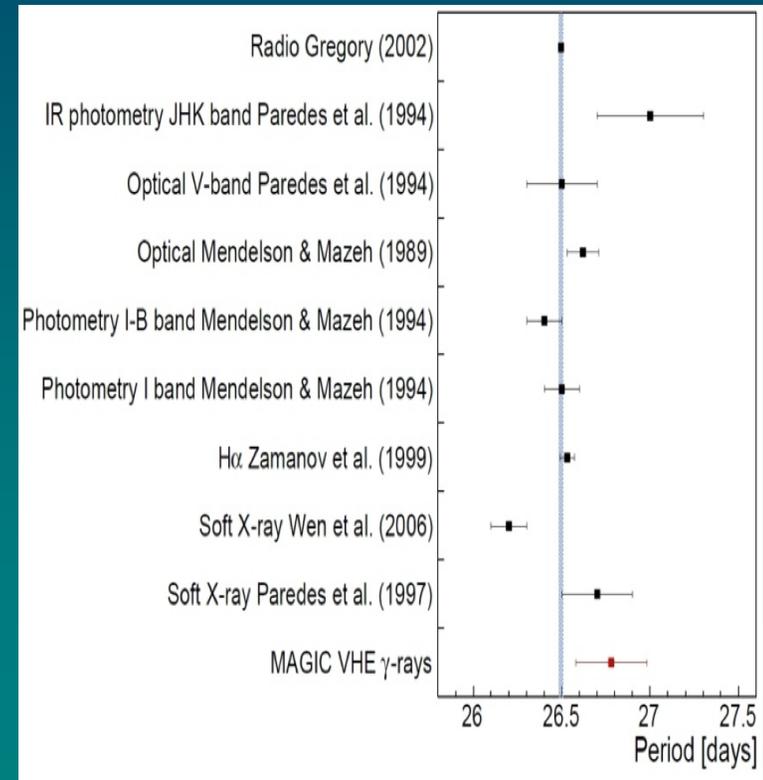

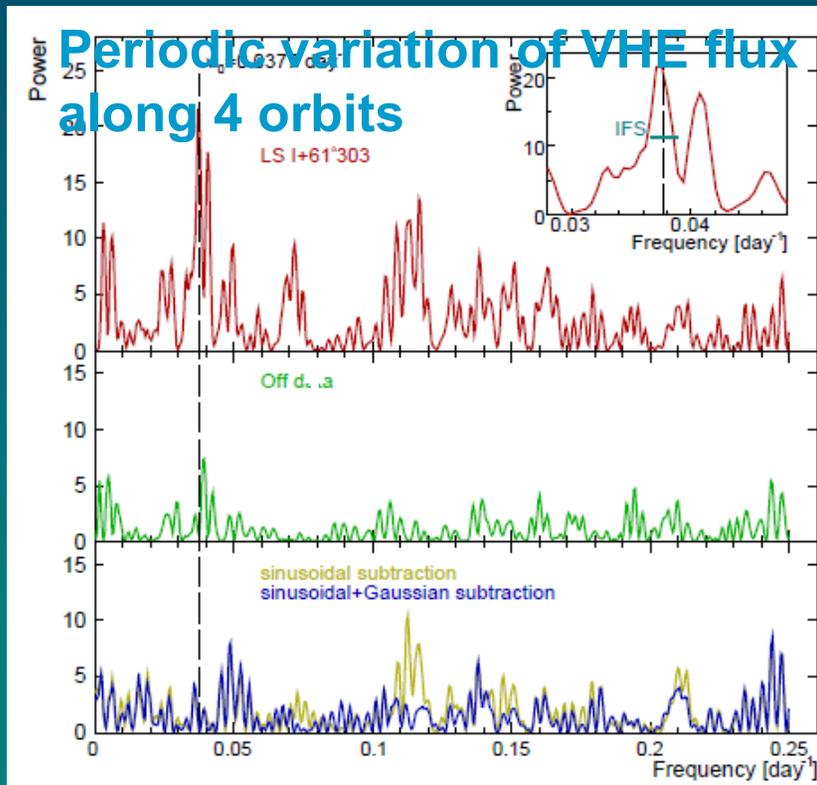

The GeV - TeV connection:  
The Crab Nebula can be used as cross-calibration source  
→ reduce uncertainty in the energy scale of IACTs

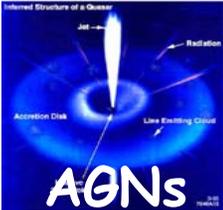

# LSI+63 303: Is the LC periodic?

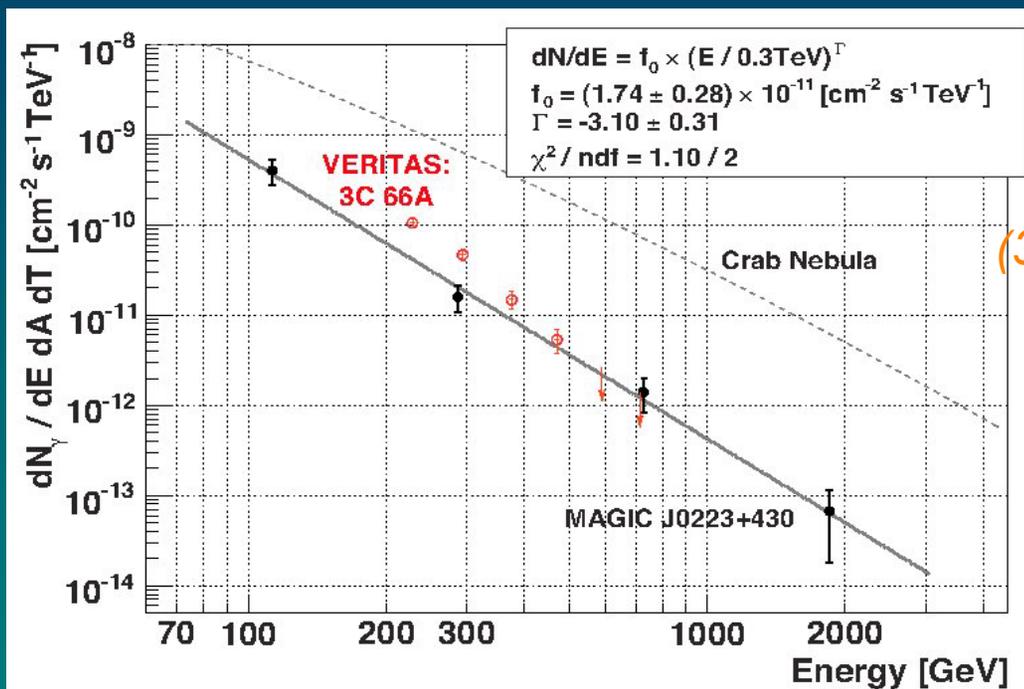

- Periodicity test reveals highly significant period  
 $P = 26.8 \pm 0.2$  days
  - consistent with emission at other wavelengths

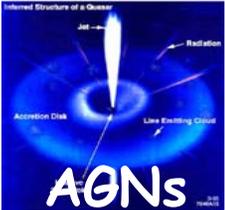

# Observations in the vicinity of 3C 66A

$F(E > 150 \text{ GeV}) \sim 2.2\% \text{ Crab} \rightarrow$  lowest ever detected by MAGIC  
 (Cannot exclude contribution of 3C 66A at lowest energies)

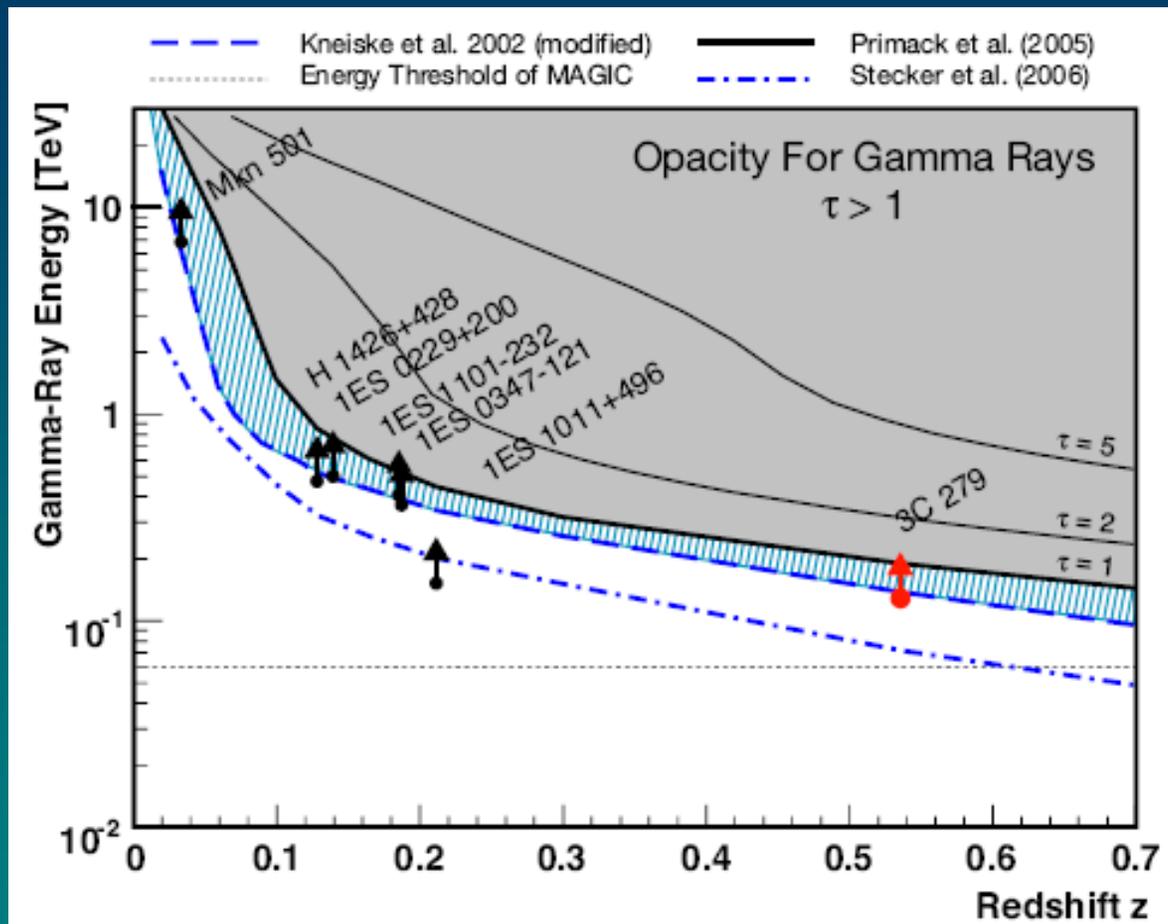

*VERITAS spectrum*  
*(3C66A) index: 4.1+/-0.4+/-0.6*

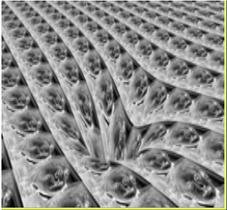

If 3C66A (unlikely)  $\rightarrow$  distance cannot be  $z > 0.23$  (no  $> 1 \text{ TeV } \gamma$ -rays, EBL)  
 Hard spectra possible, but require unusual blazar energetics ( $L > 10^{47} \text{ erg s}^{-1}$ )

# 3C279 and the $\gamma$ -ray horizon

Test of the transparency of the universe extended to  $z = 0.536!$

# Fundamental physics

MAGIC

## Energy-delayed flare of Mrk501

- Quantification of the delay:

$$\Delta t = 0.030 \pm 0.012 \text{ s/GeV}$$

Probability of no delay: 2.6%

- Possible explanations:

- Astrophysical: intrinsic source effects

- photons at different energies were emitted simultaneously:

Propagation effect due to Lorentz invariance violation:

$$c' = c \left[ 1 \pm \xi \frac{E}{E_s} \pm \zeta \left( \frac{E}{E_s} \right)^2 \right] \quad \Delta t \approx \frac{\Delta E}{E_s} \frac{L}{c}$$

→ Probing the Planck energy scale
