

# UPGRADE OF THE LNS FACILITIES

The CS upgrade with the implementation of the extraction by stripping opens up new appealing possibilities using both stable or unstable beams produced by projectile fragmentation

- **Design and realization of a new in flight fragment separator** to allow for an improvement in the transport efficiency of exotic beams to experimental areas
- **Improvement/upgrade of the existent LNS experimental set-up (MAGNEX, CHIMERA)**
- **Development of new devices: helical orbit spectrometer**

# LNS map

## FRAISE: FRAgment In-flight SEparat or

- New beam line designed to optimize beam transport of new high intensity CS beams and fragmentation products
- Radioprotections issues: production target in a shielded area operating at lower pressure

# FRAISE: the new LNS fragment separator

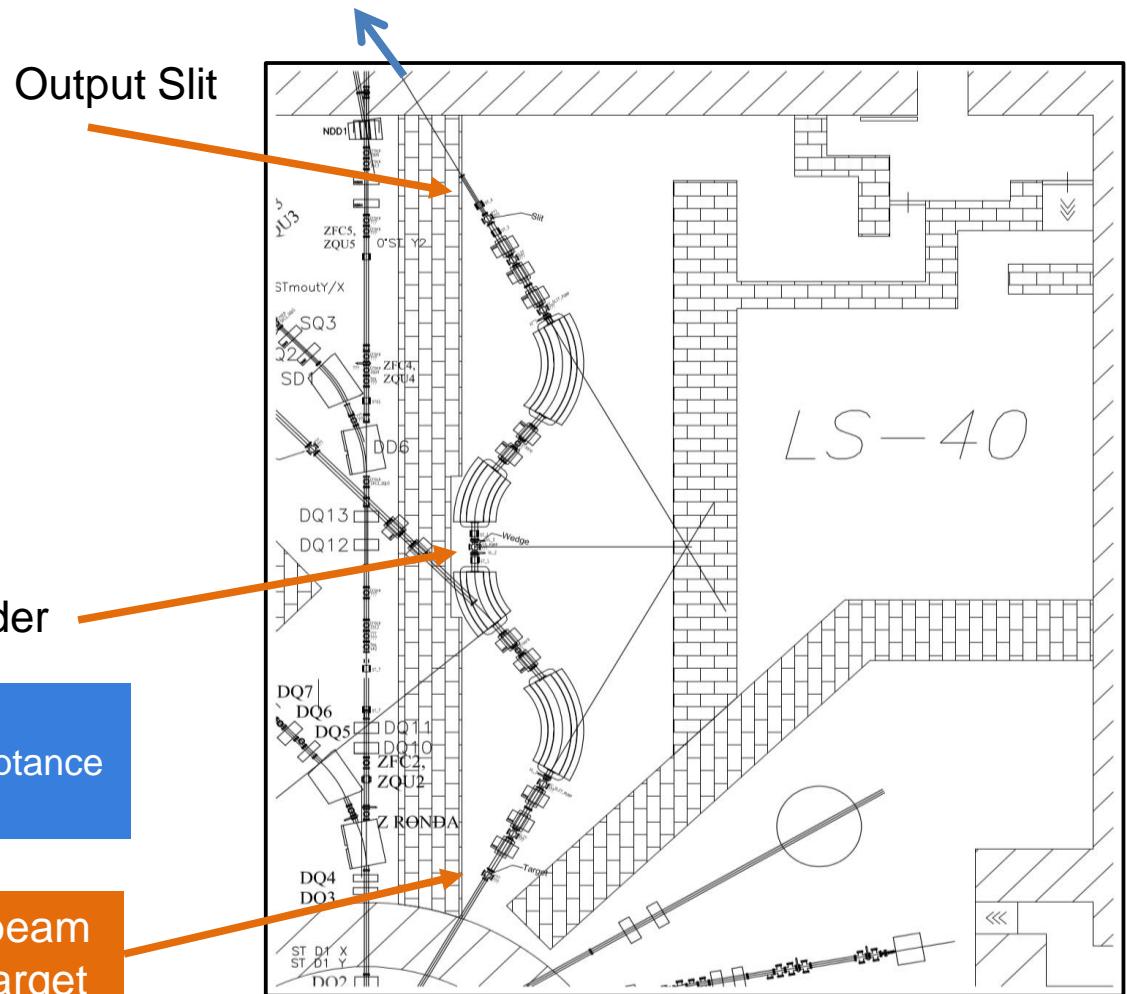

The new fragment separator consists of:

- 2 - 70° dipoles       $R=2000$  mm
  - 2 - 40° dipole       $H=\pm 200$  mm
  - 2 triplets
  - 2 doublets
- Bore  $\varnothing 140$  mm

Performances relative to FRIBS:

- Gain of a factor 5 in momentum acceptance
- Gain of a factor 2 in resolving power

## Beam line to Magnex and CHIMERA

Secondary beam  
production target

# LNS experimental set up

## MAGNEX spectrometer

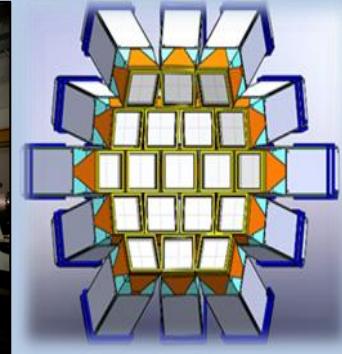

- NUMEN project
- GMR

## CHIMERA

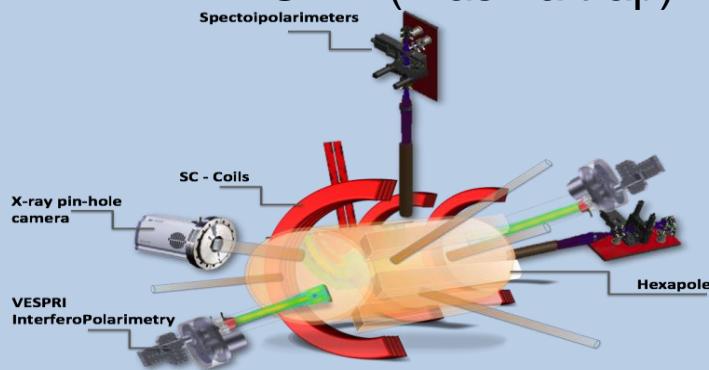

## FARCOS

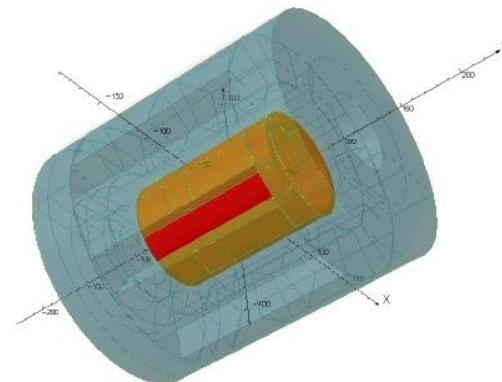

- ISOSPIN physics
- Cluster structure in nuclei
- Femtoscopy (see E. De Filippo talk)

## PANDORA (Plasma trap)

Online production of radionuclides, trapping in magnetoplasma and study of decay times vs ionization states

## Helical orbit spectrometer using SOLE

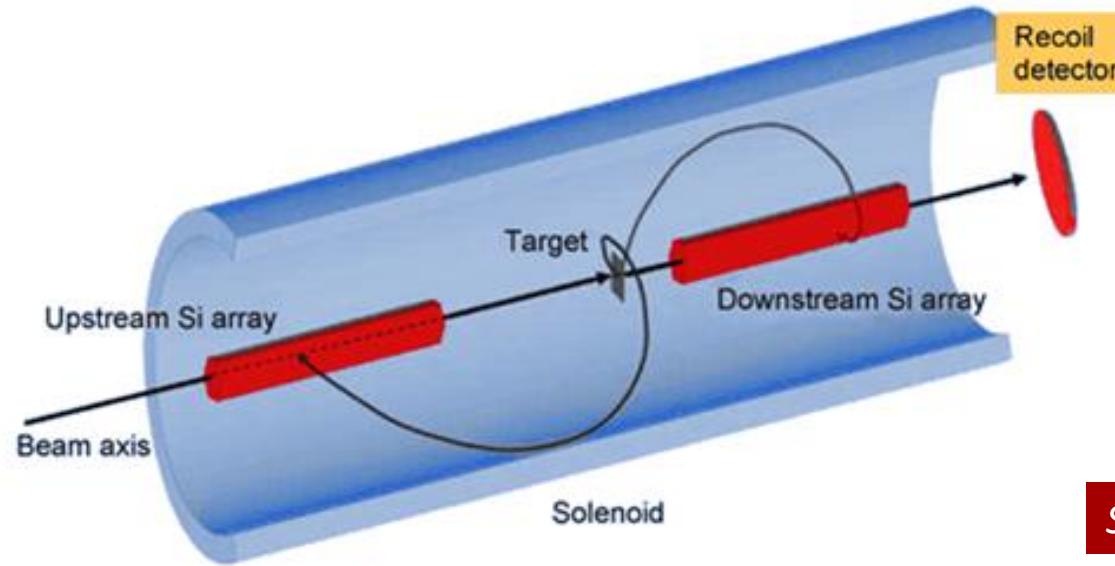

Nuclear structure of exotic nuclei

# Helical Orbit Spectrometer

## MAIN IDEA:

- Large-bore solenoid with a magnetic field (2-5 Tesla), uniform in the volume
- Beam intercepts a target inside the solenoid along its magnetic axis
- Light charged particles ejected from the target follow an helical orbit and are focused on the solenoid main axis.
- Detection: position sensitive Si array placed around the beam axis allowing for beam transport and recoil measurement

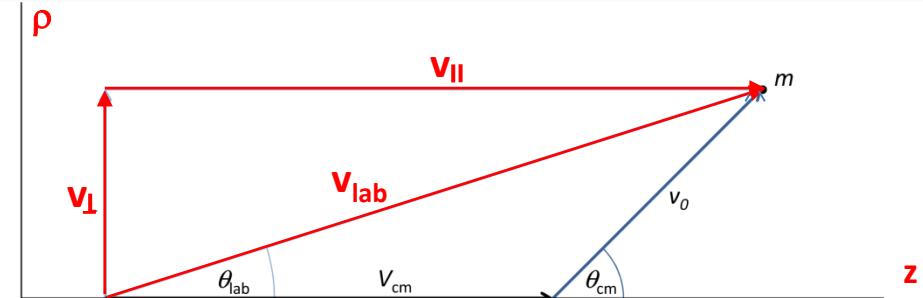

Scheme HELIOS

**Ideal tool to study direct reactions in inverse kinematics**  
(HELIOS@Argonne, ISS@ISOLDE)

# Solenoid Kinematics

Particles trajectories can be defined by the orientation of the  $\vec{V}_{\text{lab}}$  relative to solenoid axis

$v_{\perp}$  defines the radius of cyclotron motion for a particle of mass  $A$  and charge  $q$  in  $B$  field

$$r = v_{\perp} \frac{m}{qB}$$

$$T_{\text{cycl}} = \frac{2\pi r}{v} = \frac{2\pi m}{Bq} = \frac{65.6 m}{Bq} \text{ (ns)}$$

The position at which particles return to solenoid axis varies according to:

$$z = v_{\text{par}} T_{\text{cyc}}$$

What we need to measure:

- Particles ToF
- Impact point  $z$
- $E_{\text{lab}}$

Derived quantities:

- $m/q$
- $E_{\text{cm}}$
- $\Theta_{\text{cm}}$

$$\Theta_{\text{cm}} = \arccos(qeBz - 2\pi m V_{\text{cm}}) / (2\pi\sqrt{2mE_{\text{lab}} + m^2V_{\text{cm}}^2 - mV_{\text{cm}}qeBz/\pi})$$

$$E_{\text{cm}} = E_{\text{lab}} + 1/2mV_{\text{cm}}^2 - V_{\text{cm}}eqBz/2\pi$$

# Helical Orbit Spectrometer: from $(E_{\text{lab}}, \Theta_{\text{lab}})$ to $(E_{\text{lab}}, z)$

## Advantages:

- Particle identification through  $\text{ToF} = T_{\text{cycl}}$
- Enhanced Q-value resolution
- No kinematical compression effects ( $\Delta E_{\text{lab}} = \Delta E_{\text{cm}}$ )

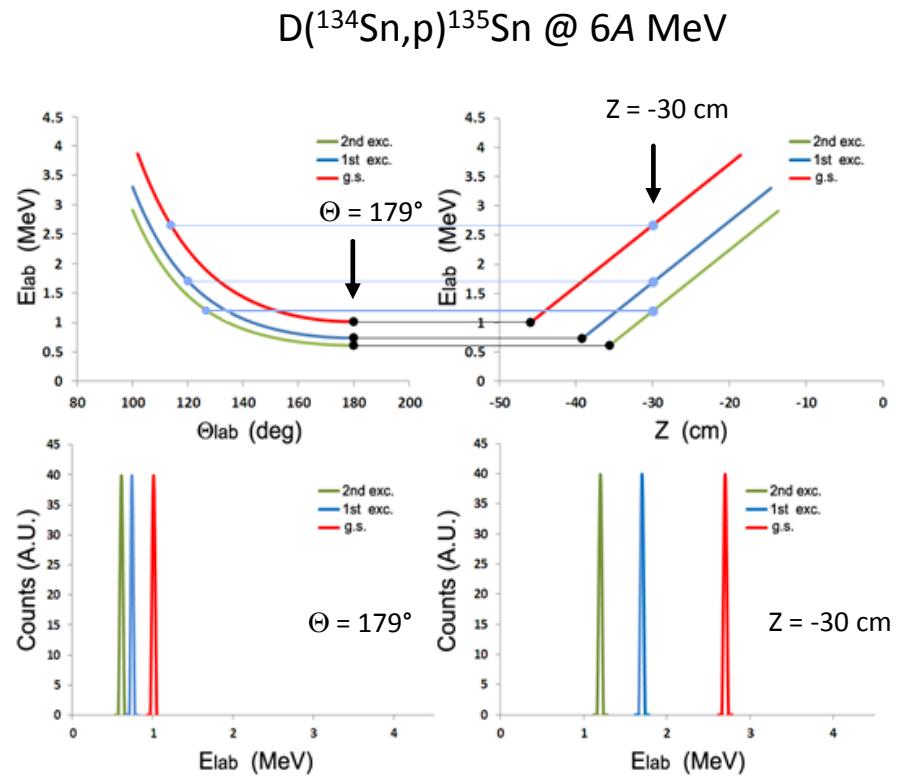

Ion	$T_{\text{cycl}} = \text{ToF}$ (ns)
B = 2 Tesla	
p	32.8
d, Alfa <sup>2+</sup>	65.6

What it can be studied depends on :

- Two-body Kinematics
- Solenoid Size
- Solenoid B intensity
- Array

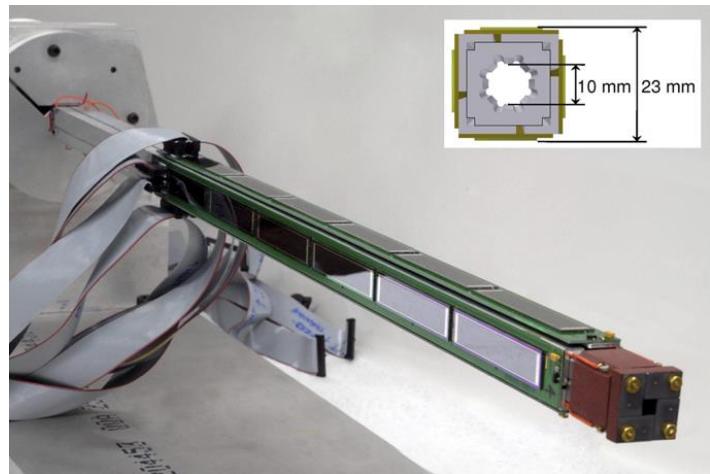

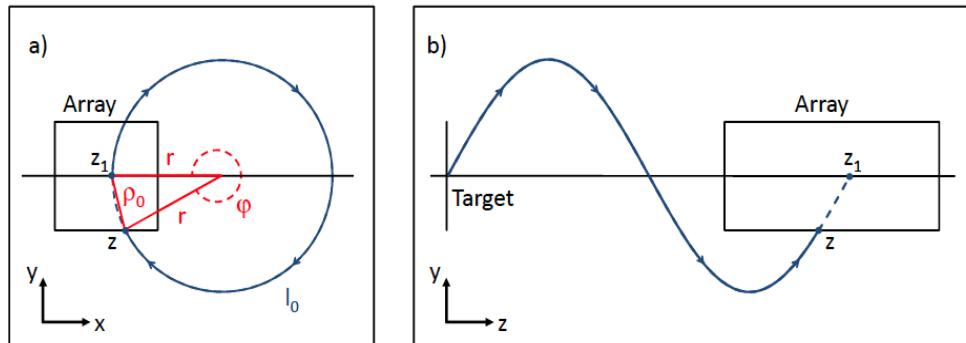

The quality of the results:

- B field degree of homogeneity
- type/shape of the detection array
- beam energy resolution
- beam spot size
- target thickness

SOLE axial magnetic field in OPERA

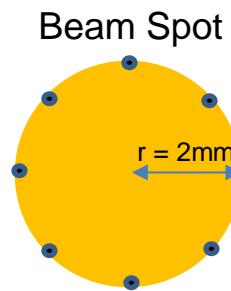

Z impact point of protons vs theta

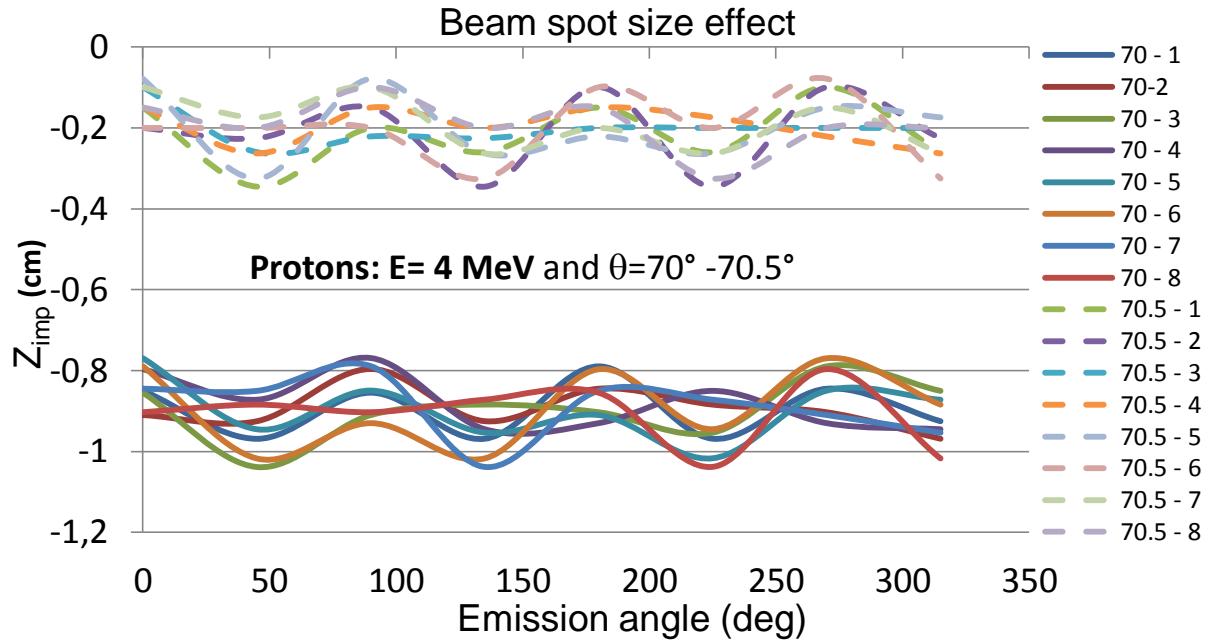

# Study of an Helical Orbit Spectrometer @ LNS

# Beam size effects

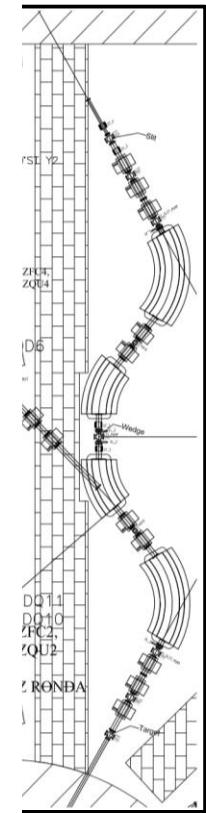

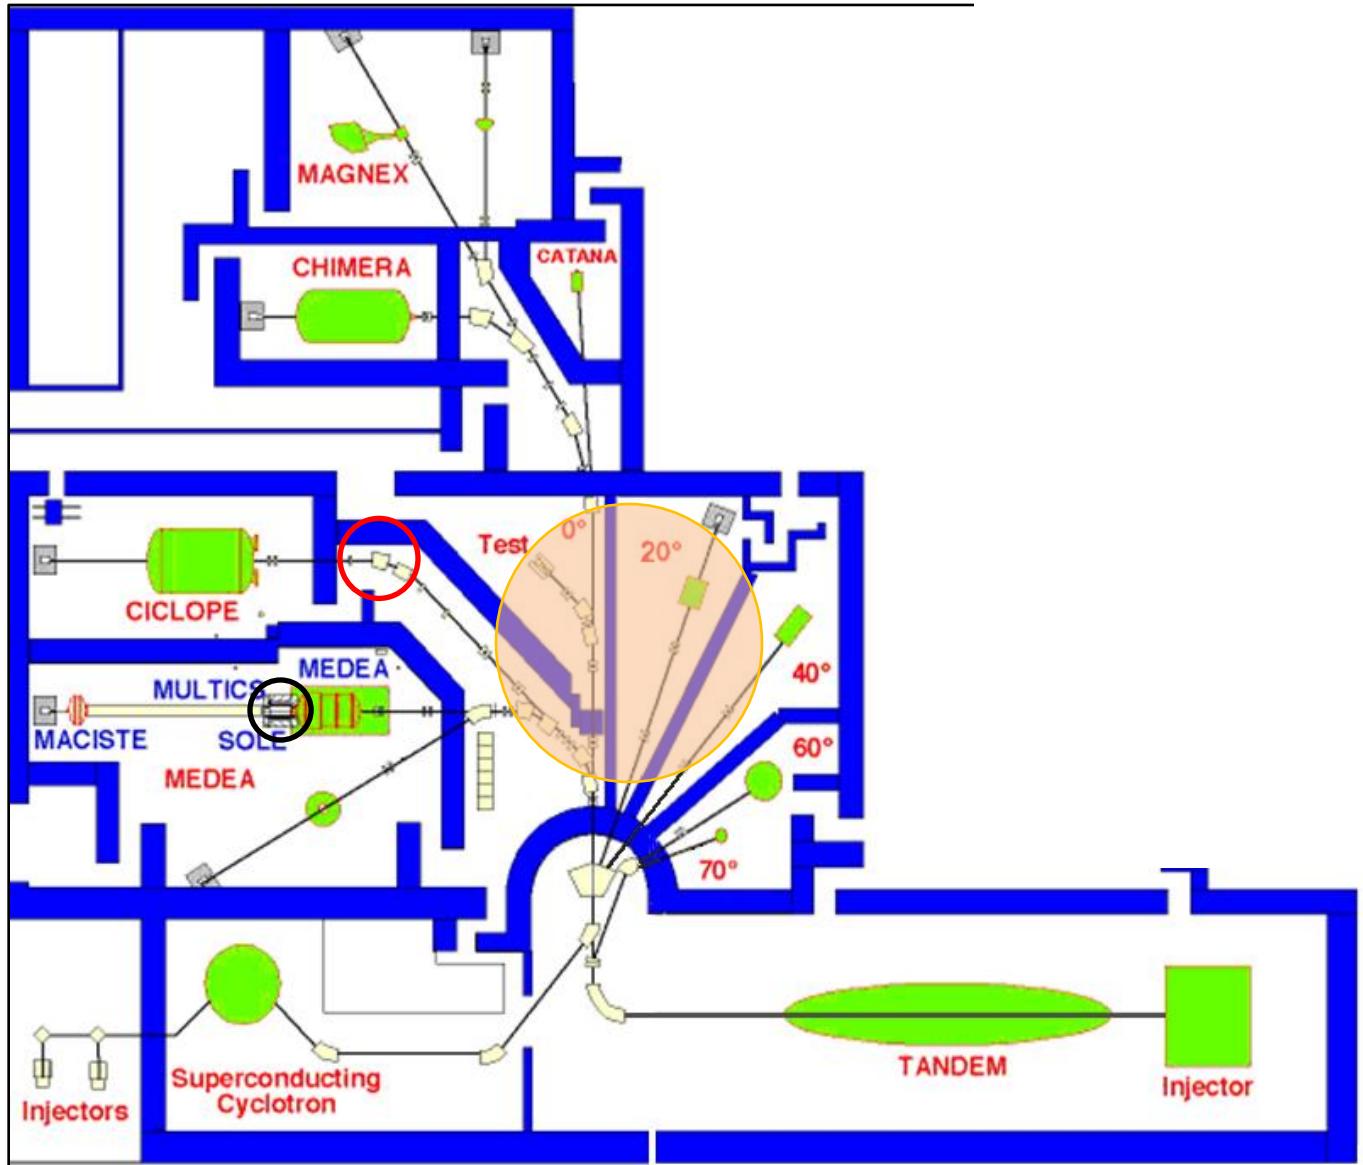

Protons:  
 $E = 4 \text{ MeV}, \theta = 70^\circ$   
 $E = 4 \text{ MeV}, \theta = 70.5^\circ$

### Future activities:

- Detailed map of the magnetic field
- Charged particles transport simulations with measured field
- Test of the performances with a tandem beam

# Study of an Helical Orbit Spectrometer @ LNS

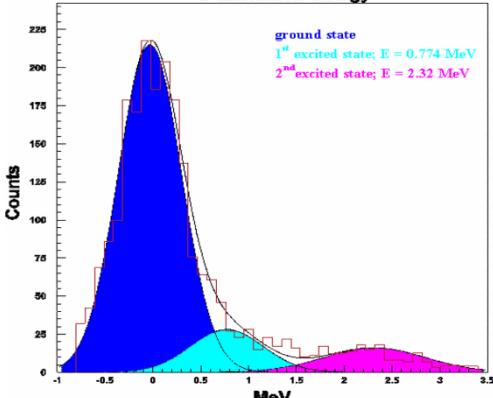

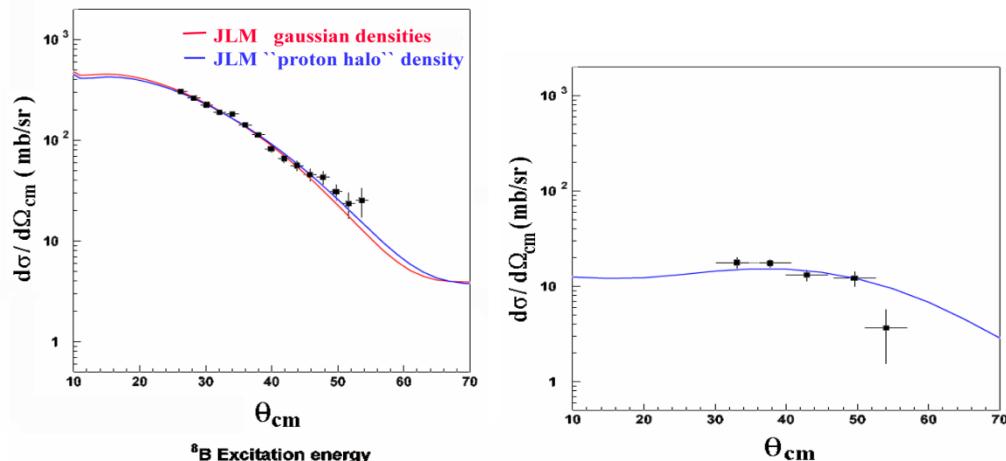

A.Russo

# Physics case: existence of proton halo in ${}^8\text{B}$ through (p,p') scattering

Studies of  ${}^8\text{B}$  structure through momentum distribution of  ${}^7\text{Be}$  fragments following  ${}^8\text{B}$  breakup are not conclusive concerning the existence of halo (MSU and GSI exp.)

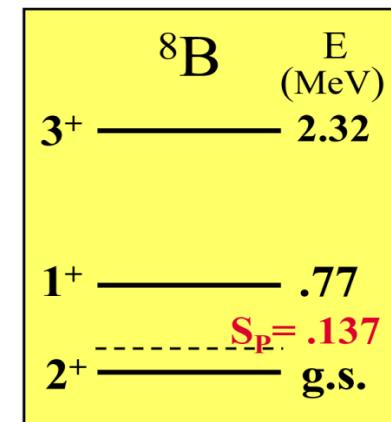

Quasi elastic scattering of  ${}^8\text{B}$  on  ${}^{12}\text{C}$  at GANIL doesn't support the existence of proton halo (Pecina et al. PRC52(1995) 91)

Elastic and inelastic scattering through (p,p') at MSU are coherent with the existence of a proton halo but some limitation in the data exists

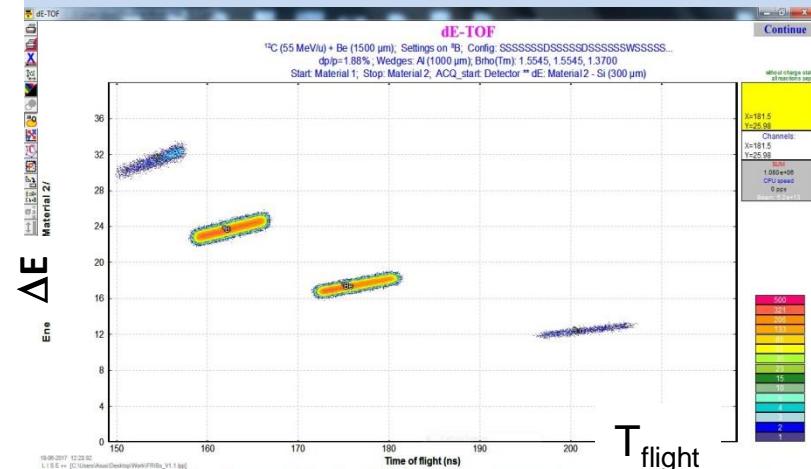

- Limited energy resolution
- Statistics at large angles

Measured  $B(E2) = 70 \text{ e}^2\text{fm}^4$   
Theoretical predictions:  
 $B(E2) = 9 \text{ e}^2\text{fm}^4$   
Study of inelastic to  $3^+$  state

Helios-like spectrometer is expected to have a much better resolution

${}^8\text{B}$  Yield with FRAISE  
Yield  ${}^8\text{B} = 1.86 \cdot 10^5 \text{ pps}$  (purity 56%)  
Main contaminant  ${}^7\text{Be}$

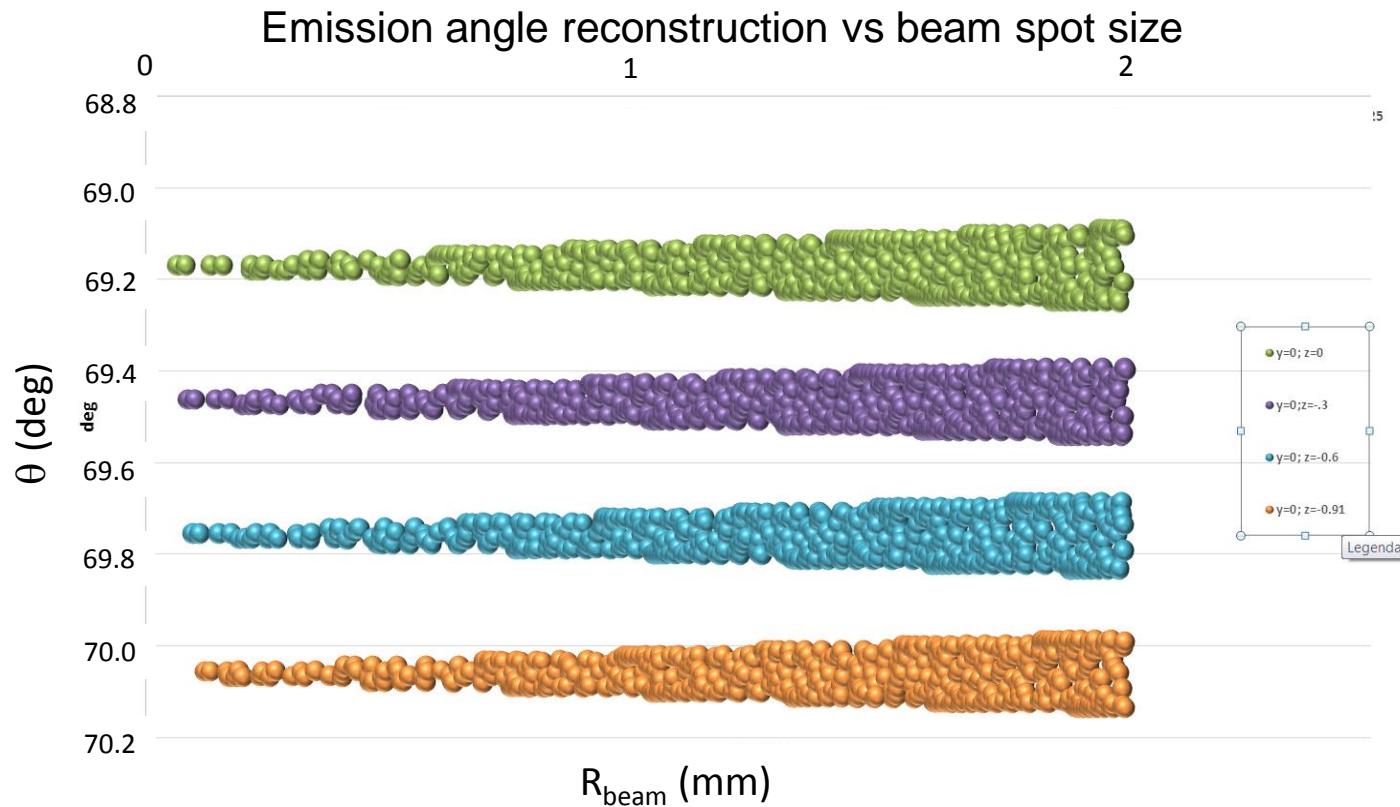

# Summary

- Upgrade of FRIBS and detectors
- Helical orbit Spectrometer
- Main advantages of ( $E_{lab}, z$ ) detection
- Detection Array main features
- Study of an Helical Orbit Spectrometer @ LNS
- Applications to exotic nuclei

# Study of an Helical Orbit Spectrometer @ LNS

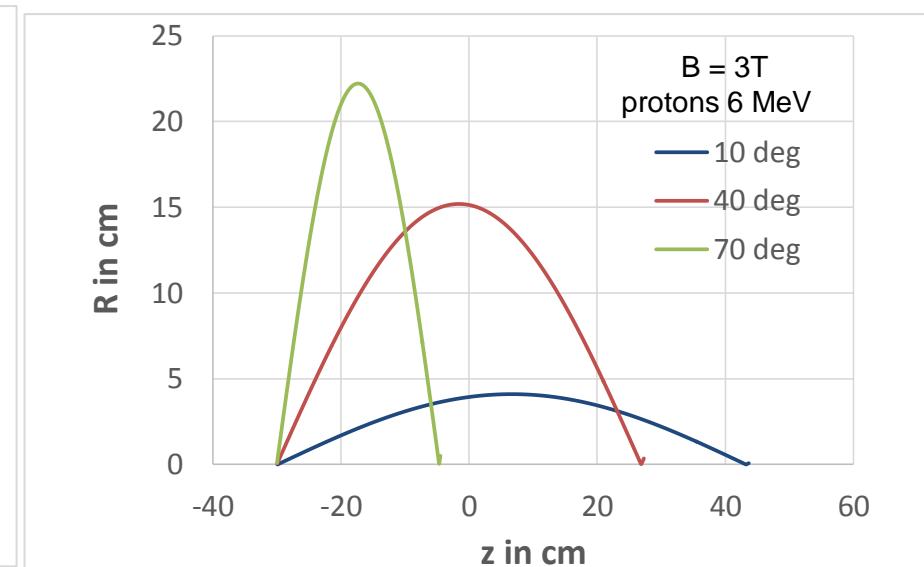

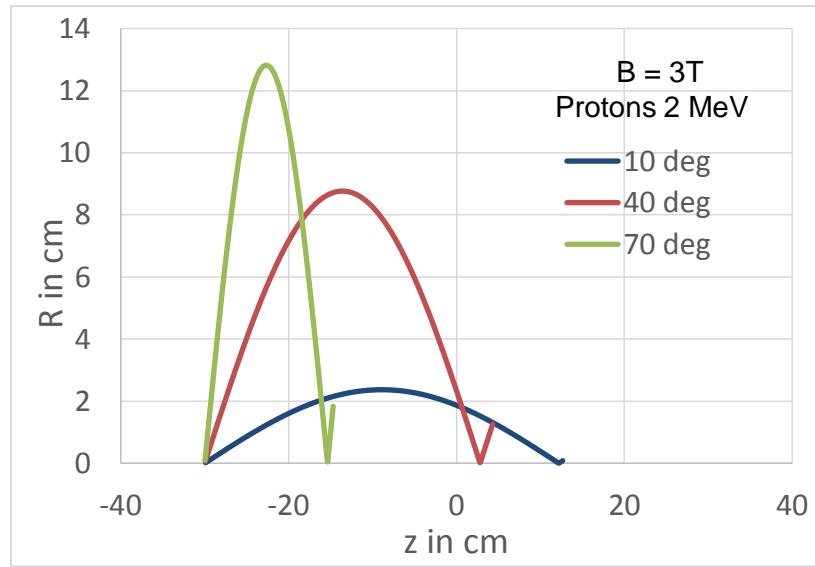

# Solenoid magnetic field homogeneity

Helios uses a solenoid built for NRM with a B field homogeneity of the order  $10^{-4}$

Region of homogeneity Length  $\approx 2$  Radius

Simulations: Solenoid with a degree of homogeneity of the order of  $10^{-3}$  and  $10^{-4}$

$$\Delta x (\text{Sole\_ideal} - \text{Sole}_{10^{-3}}) = f(E, \Theta_{\text{lab}})$$

Es: proton 6 MeV,  $\Theta_{\text{lab}}=10^\circ$   $\Delta x= 1.2$  mm

$$\Delta x (\text{Sole\_ideal} - \text{Sole}_{10^{-4}}) = f(E, \Theta_{\text{lab}})$$

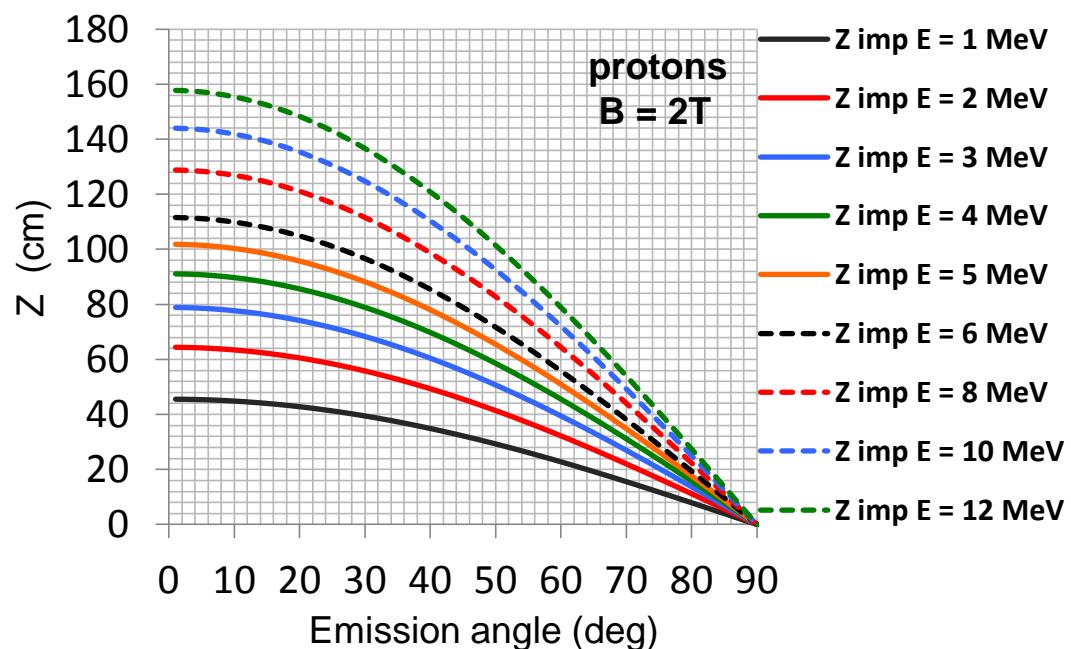

Es: proton 6 MeV,  $\Theta_{\text{lab}}=10^\circ$   $\Delta x= 0.5$  mm

# Solenoid

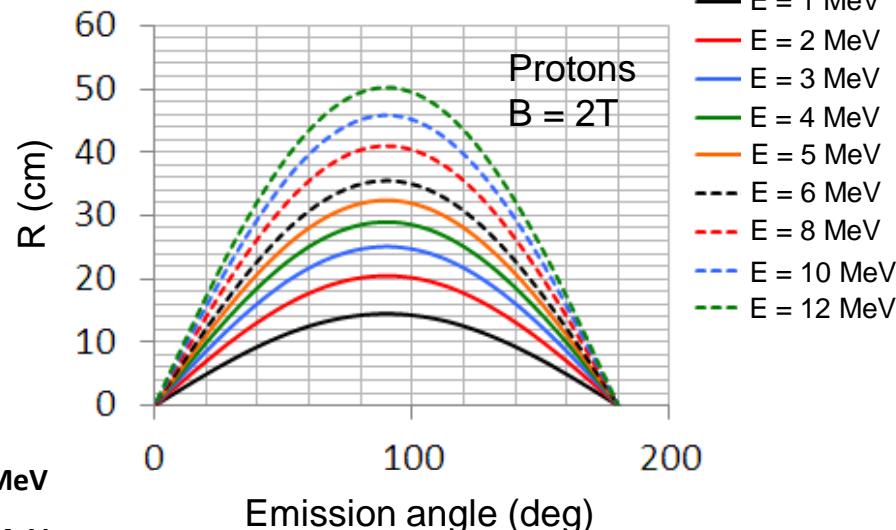

Main parameter governing spectrometer acceptance :

- B intensity
- Radius( $R$ )
- Length ( $L$ )
- The extent of the magnetic field and array geometry imposes limits on the acceptance region

Impact point along the solenoid axis

$R_{max}$  from solenoid axis (cm)

## Requirements:

- Variable field to optimize the focalization of particles (p,d,t,a) on the detector array
- Homogenous field size:  
Radius 40 cm  
Length  $\sim 100-120$  cm

# Helical Orbit Spectrometer: applications

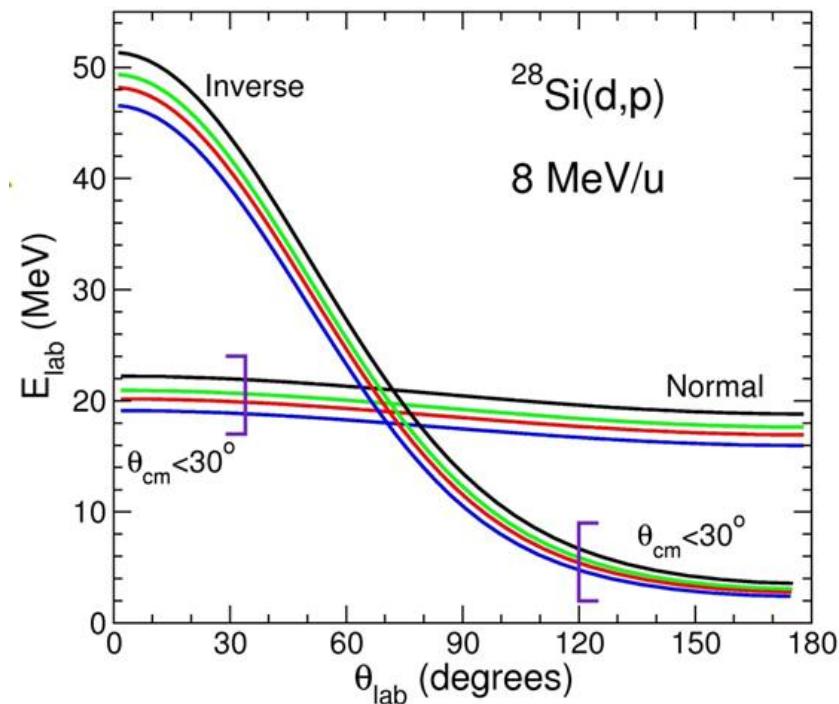

Nuclear structure studies with low intensity beams → direct reactions

- Elastic Scattering (density distribution of p,n)
- Inelastic Scattering (excited states, collectivity,  $B(E2),B(E3)$ )
- One nucleon transfer (single particle states, astrophysical processes)
- Two nucleon transfer (pair correlations)

Two-body reactions in inverse kinematics: easier to detect the light reaction partner

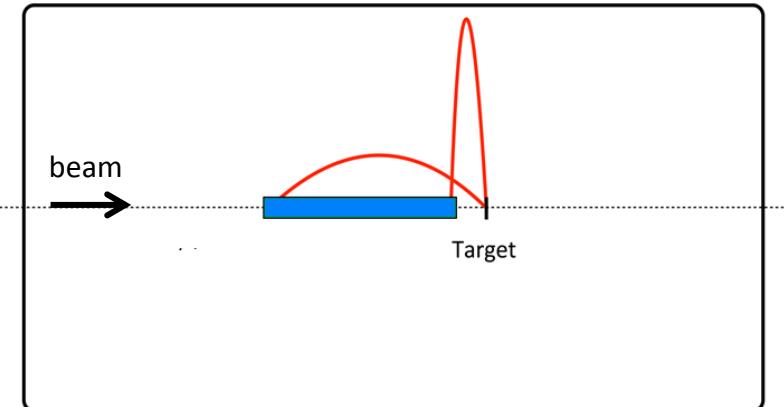

Problems:

- Low energy particles - identification
- Strong angular dependence
- Kinematical compression at large lab. angle
- Low intensity beam (detection efficiency)

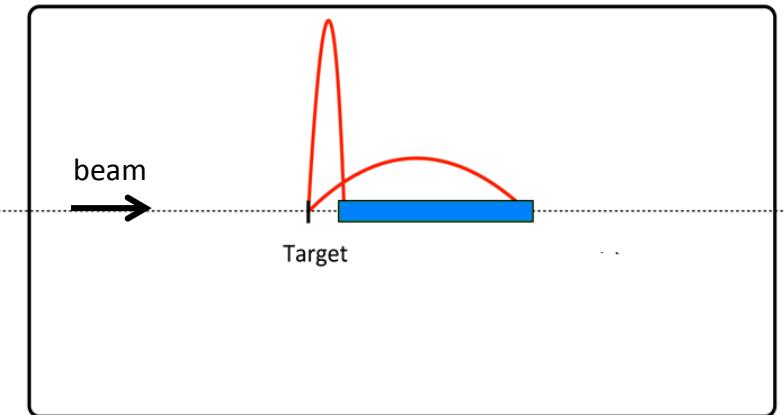

# Detection system: Si array

Array geometry depends on the kinematics

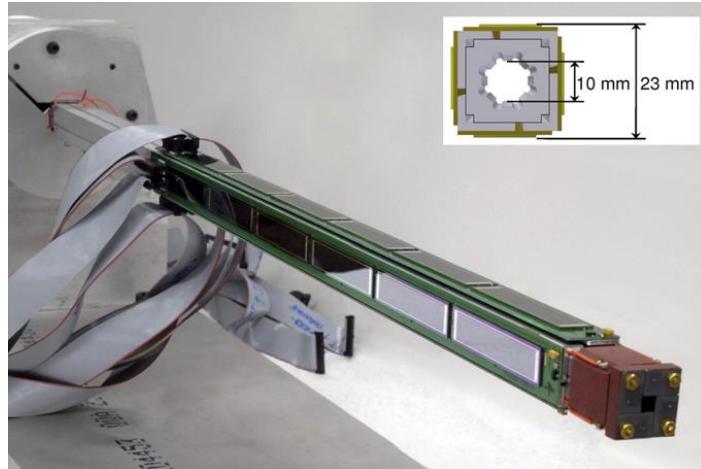

Es:(d,p) (t,p) ( ${}^3\text{He}$ ,d) ( ${}^3\text{He}$ , $\alpha$ )

Es: (p, $p'$ ) (p,d) ( ${}^3\text{He}$ ,t)

Setup Si di HELIOS

## Detectors:

- Position sensitive Si, thickness: 1000-1500  $\mu\text{m}$

## Geometry:

- Array with a regular polygonal cross-section
- Array lenght: 500 – 800 mm
- Two opposite requirements (beam trasport – particle detection)
