

EMCal Trigger Simulation

EMCal Software Meeting
Laboratorio Nazionale di Frascati
May 19-21, 2009

Rachid GUERNANE
LPSC Grenoble CNRS/IN2P3

EMCal Layout

ALICE official coordinate system see ALICE-INT-2003-038

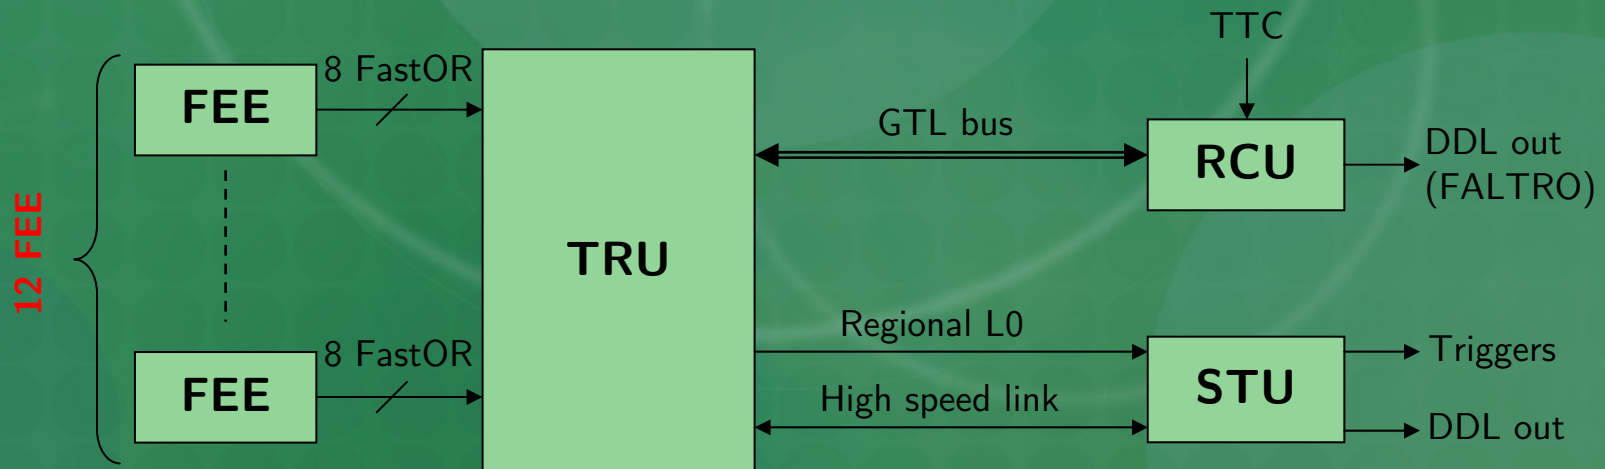

48 towers (24 FastOR)

0	4	8	12	16	20	24	28	32	36	40	44	48	52	56	60	64	68	72	76	80	84	88	92
1	5	9	13	17	21	25	29	33	37	41	45	49	53	57	61	65	69	73	77	81	85	89	93
2	6	10	14	18	22	26	30	34	38	42	46	50	54	58	62	66	70	74	78	82	86	90	94
3	7	11	15	19	23	27	31	35	39	43	47	51	55	59	63	67	71	75	79	83	87	91	95

TRU ADC Mapping

EMCal Trigger in a Nutshell

- **L0 (1.2 μs after interaction)**
 - Energy summed over sliding window of 4×4 towers (2×2 FastOR) and compared to a threshold above noise
- **L1- γ (6.5 μs after interaction)**
 - Energy summed over sliding window of 4×4 towers (2×2 FastOR) and compared to a multiplicity dependent threshold (from V0)
- **L1-j**
 - Energy summed over a sliding window of $n \times n$ subregions and compared to a multiplicity corrected threshold (a subregion is defined as 8×8 towers)

Level-0 threshold trigger

L1 is working w/ time sums

L1- γ processing

- Patch size is similar to the L0 one
- But EMCAL is scanned over its whole surface (no TRU border limit as in the L0 case)

TRU# n

0	4	8	12	16	20	24	28	32	36	40	44	48	52	56	60	64	68	72	76	80	84	88	92

Patch
⇒ 3×3 subregions

V0 Interface

V0 crate

- Physical layer OK
- Protocol agreed
 - 2×11 bit word transfer: A plate and C plate charge
 - Transfer initiated by CTP confirmed L0
 - V0 can provide charge values at the L0/L1a rate
 - EMCAL doesn't need to implement specific test mode for timing adjustment
- V0 DCS will made the HV setting available for STU DCS
 - Optimal threshold equation parameter can be computed before each run by DCS

EMCal present trigger simulation in AliRoot

- The 'all-in-one' `AliEMCALTrigger` class
 - No more in line w/ real Hw design
 - FastOR shaping is wrong! (use the FEE one, H/L gain?)
 - Trigger definitions are outdated
 - `_GammaHPt_L1`, `_GammaMPt_L1`, `_GammaLPt_L1`
 - Thresholds are fixed...
 - one L0, $N \geq 5$ (?) hardcoded for L1- j , 2 (H/G gain) for L1- γ
 - ...but the patch energy is corrected from V0 multiplicity (retrieved from ESD)
 - Some 'unknown' legacy code possibly not feasible from the Hw point of view
 - Method `IsPatchIsolated()`

New implementation from scratch

- Constrain
 - Ability to recompute off/on-line the trigger response from Fake-ALTRO data for trigger monitoring
- EMCAL trigger package
 - Set of 8 new classes

```
class AliEMCALTrigger
class AliEMCALTriggerBoard
class AliEMCALTriggerTRU : AliEMCALTriggerBoard
class AliEMCALTriggerSTU : AliEMCALTriggerBoard
class AliEMCALTriggerPatch (x, y, sum)
class AliEMCALTriggerData
class AliEMCALTriggerParam
```

AliEMCALTrigger

- Replaces the old AliEMCALTrigger class but acts now as manager class only
 - Creates AliEMCALTriggerTRU objects (32)
 - Creates AliEMCALTriggerSTU object
 - Reads tower digits and sends them to the TRUs
 - TRU index is computed from tower id using
`AliEMCALGeometry::GetCellIndex()` and
`AliEMCALGeometry::GetModulePhiEtaIndexInSModule()`
 - Issue L0 calculations and if one L0 is found issue L1 calculation
 - Fill L0/L1 data in digit tree

AliEMCAL Trigger Board

- Trigger boards base class
 - Region (made of FastOR) instantiation (array of int)
 - Subregion, patch size setters
 - Windowing algorithm running for both L0 & L1

AliEMCAL Trigger TRU :

AliEMCAL Trigger Board

- Analog FastOR recipe

- Start from tower energy deposit
from module digits summing fDE_{primary}  Digits of amplitude below a given threshold are removed
- Light yield (from EMCAL TDR) 125 photo- e^- /MeV at M=30
- CSP response (from EMCAL TDR) 0.136 $\mu\text{V}/e^-$
- FastOR shaper transfer function
computed from FEE circuitry
- Phase shift due to ToF + cable length towards FEE crate

- Digital FastOR

- Sampling frequency 40MHz
- ADC FSR 0-1V
- ADC resolution 11 bits
- Noise can be generated according to a multivariate Gaussian if samples are correlated
To be checked from pedestal data

- L0 algorithm 

- For each time window
Sliding patch of 2×2 FastOR
Trigger is issued if patch energy is above threshold and patch energy has reached a maximum ('2-up/1-down' condition)

AliEMCALTriggerSTU :

AliEMCALTriggerBoard

- Fill its internal data (full EMCAL region) from TRU FastOR (time sums) on L0 issuing
- Read V0 digits & OCDB to estimate V0 A&C multiplicities
- Compute V0 threshold = $f(V0A, V0C)$
- Sliding window
 - L1- γ 2×2 subregions (subregion is 1×1 FastOR)
 - L1- j 3×3 subregions (subregion is 4×4 FastOR)

AliEMCALTriggerData

- Contain the triggering data to be stored in digit tree for post-processing
- Make a trigger branch and write
 - List of L0 patches
 - List of L1- γ patches
 - List of L1- j patches
 - EMCAL region FastOR built from TRU inputs
 - V0 A&C multiplicity estimates

Still have some problem to update digit tree

AliEMCALTriggerParam

- Contains parameters for trigger calculation having in mind Hw limitations (not all Sw parameters can be Hw parameters)*
 - Subregion, patch sizes*
 - FastOR response (rise time, ADC FSR...)
 - Time window width...
- Could move pieces from `AliEMCALGeometry` regarding trigger mapping to be independent of pure geometry parameters (G3)

What's next?

- Simulate TRU data to be injected in the STU firmware
 - Generate DDL data packets decoded back in simulation (use `class AliEMCALSTURawStream`) and check consistency
- Define trigger calibration data and R/W from/to OCDB
 - L0 thresholds
 - L1 thresholds parameters $f(V0)$
 - dead/noisy channel masks...
- Clarify the use of `AliCentralTrigger` class
- Need for HIJING events
