## Results from the CUORE experiment

*Friday, 7 June 2019 11:56 (23 minutes)*

The Cryogenic Underground Observatory for Rare Events (CUORE) is the first bolometric experiment searching for neutrinoless double beta decay ( $0\nu\beta\beta$ ) that has been able to reach the one-ton scale. The detector consists of an array of 988 TeO<sub>2</sub> crystals arranged in a compact cylindrical structure of 19 towers. The construction of the experiment was completed in August 2016 with the installation of all towers in the cryostat. Following a cooldown, diagnostic, and optimization campaign, routine data-taking began in spring 2017. In this talk, we present the  $0\nu\beta\beta$  results of CUORE from examining a total TeO<sub>2</sub> exposure of 86.3 kg·yr, characterized by an average energy resolution of 7.7 keV FWHM and a background in the region of interest of 0.014 counts/(keV·kg·yr). In this physics run, CUORE placed the current best lower limit on the <sup>130</sup>Te  $0\nu\beta\beta$  half-life of  $> 1.3 \times 10^{25}$  yr (90% C.L.). We then discuss the additional improvements in the detector performance achieved in 2018, the latest evaluation of the CUORE background budget, and we finally present the most precise measurement of the <sup>130</sup>Te  $2\nu\beta\beta$  half-life to date.

### Collaboration name

CUORE

**Primary authors:** SINGH, Vivek (University of California); CUORE COLLABORATION

**Presenter:** SINGH, Vivek (University of California)

**Session Classification:** Neutrino

**Track Classification:** Neutrino Physics
