

$B_0 \rightarrow \eta' K_0$: study on ΔT resolution.
and first test of TreeFitter

Stefano Lacaprara, Alessandro Mordà

`stefano.lacaprara@pd.infn.it`

INFN Padova

8^{th} Belle II Italian collaboration meeting,
Pisa, 20 november 2017

Will talk about:

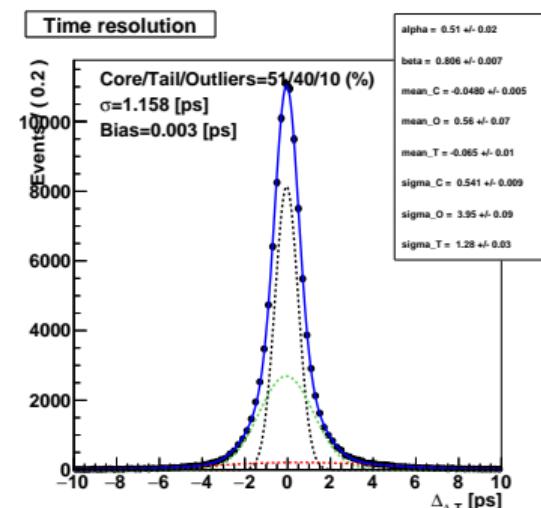

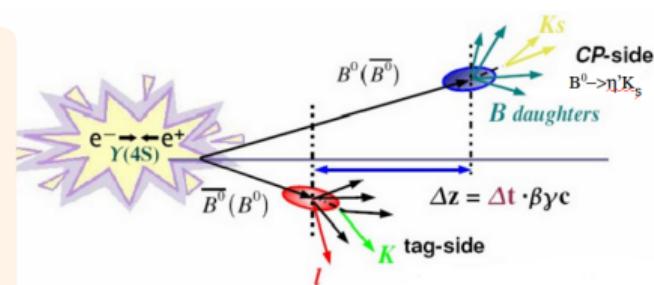

- ΔT resolution
 - ▶ analysis of structures of ΔT resolution
 - ▶ study of ΔT dependencies from other variables
 - ▶ test of advanced ΔT resolution model with B^0 lifetime τ_B
 - ▶ analysis of *per-event* $\sigma_{\Delta T}$
- First test with TreeFitter
 - ▶ Efficiency
 - ▶ resolution

Motivations:

- we want to study the ΔT resolution for $B^0 \rightarrow \eta' K^0$ final state
- assess the systematic uncertainties due to limited knowledge of ΔT resolution
- provide a better definition of ΔT reso to be used in the ML fit to extract the TDCPV parameters
- study the B^0 lifetime in the same channel τ ;
 - ▶ can be studied also in control channel $B^\pm \rightarrow \eta' K^\pm$
- So far, used a single tri-gaussian pdf

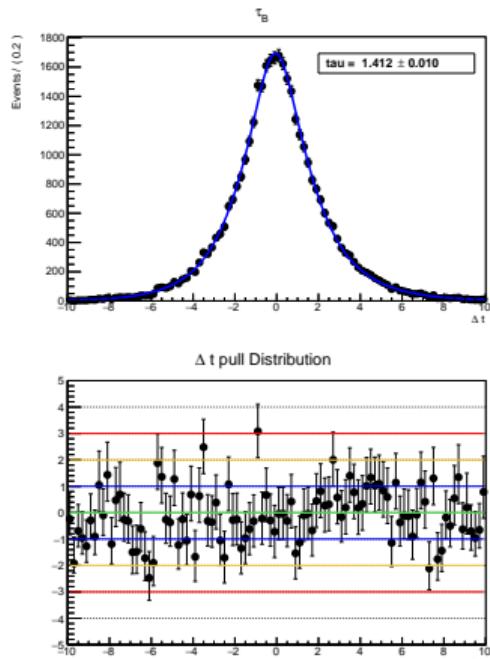

Channel: $B^0 \rightarrow \eta' (\rightarrow \pi^+ \pi^- \eta (\rightarrow \gamma\gamma)) K^0 (\rightarrow \pi^\pm)$

Tech. details: MC9, BGx0, Rel 00-09-02 with patch

τ_B tests - remind from last B2GM

Reco-level

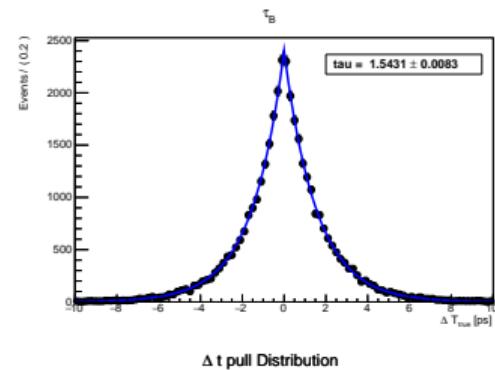

$$\tau_B = 1.412 \pm 0.010 \text{ ps}$$

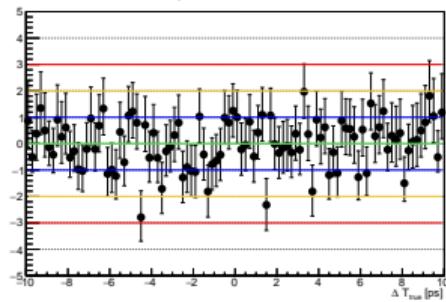

τ_B from fit to ΔT
PDF: double sided decay
function convoluted with ΔT
resolution model

There's a non negligible
underestimation of the τ_B , for
both channels ($\tau_B^{gen} = 1.534$
ps)

Gen-level

Δt pull Distribution

$$\tau_B = 1.543 \pm 0.008 \text{ ps}$$

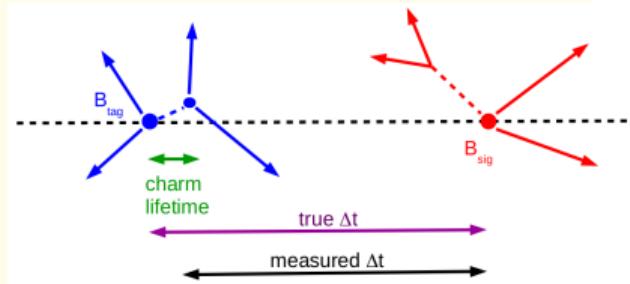

Two possible causes:

- bias due to selection or reconstruction is ruled out
- symptomatic of a wrong estimation of ΔT resolution

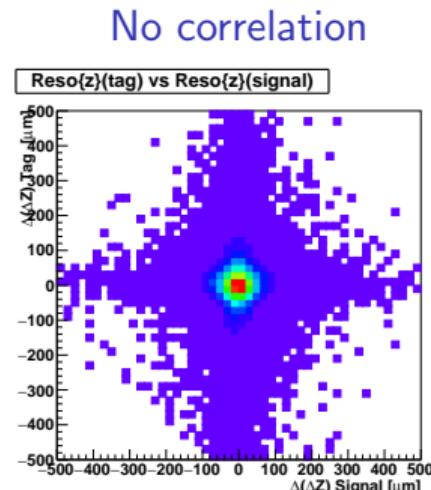

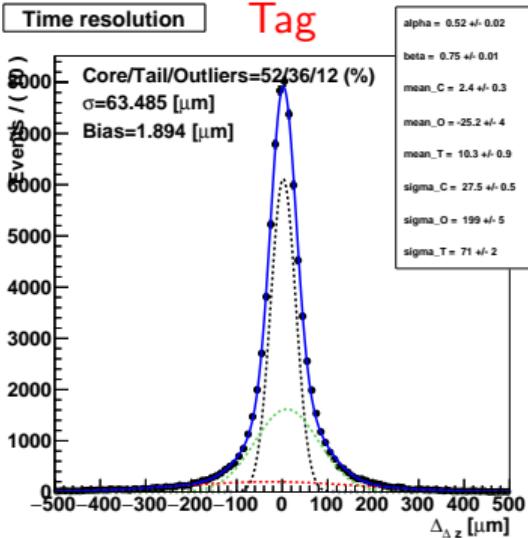

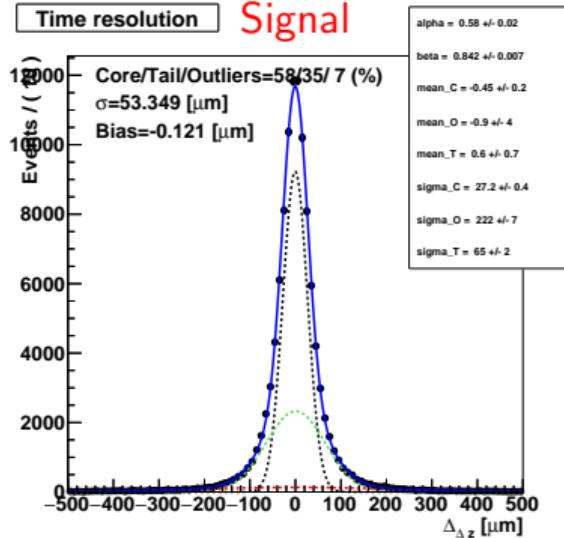

In Belle documented in [Tajima et al., 2004]

- ΔT reso is a convolution of four contributions:
 - ① z reso for B^0 vertex for signal
 - ② and tag side;
 - ③ smearing due to additional non-primary tracks (K^0 , charm);
 - ④ approx that B^0 is at rest in the cms of Belle;
- and it is a (complex) function of:
 - ▶ no. of tracks used in vertex fit (both signal and tag side);
 - ▶ error on vertex fit positions;
 - ▶ $\chi^2/NDof$ of vertices fit;

In Babar datasample was split in different categories of Flavor Tagging variable, and each category fitted separately

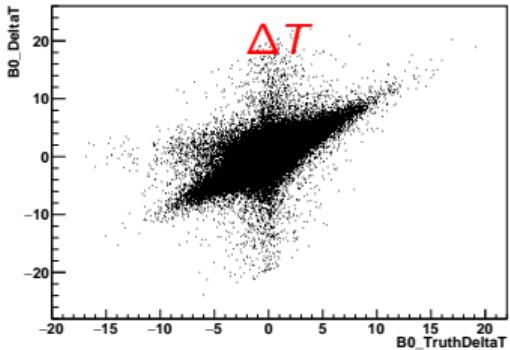

Δz resolution: Tag and signal side

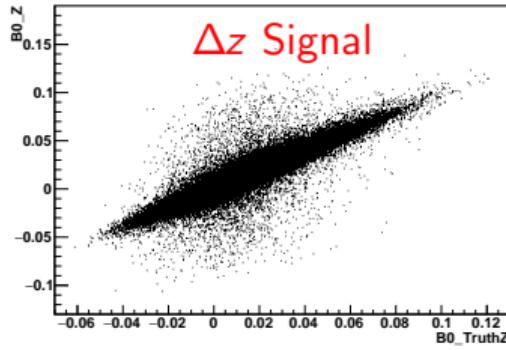

Signal side resolution depends on channel, not tag side

$\Delta T / \Delta z$ vs Truth

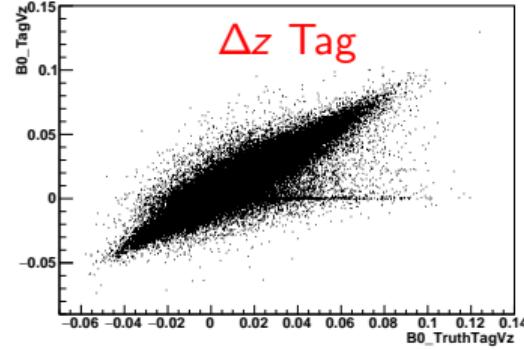

```
B0_DeltaT_B0_TruthDeltaT (B0_isSignal && abs(B0_DeltaT_B0_TruthDeltaT)<20 && abs(B0_isTag)<10 && abs(B0_TruthDeltaT)<10)
```

```
B0_Z_B0_TruthZ (B0_isSignal && B0_TagVzTruthZ<0 && abs(B0_DeltaZ)<10 && abs(B0_TruthDeltaZ)<10)
```

```
B0_TagVz_B0_TruthTagVz (B0_isSignal && B0_TagVzTruthVz<0 && abs(B0_DeltaTagVz)<10 && abs(B0_TruthDeltaTagVz)<10)
```

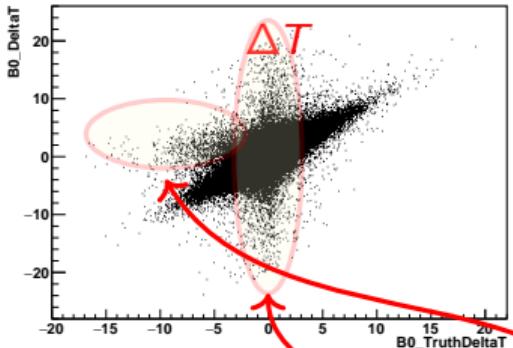

Structures visible:

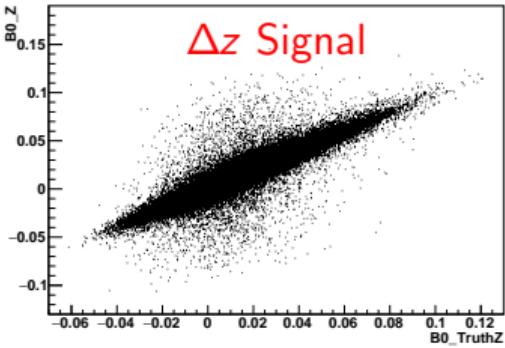

- at $\Delta T_{\text{truth}} \sim 0$ and $\Delta T_{\text{truth}} < 0$
 - ▶ origin not so clear, not so visible in Δz signal
- at $z_{\text{reco}} \sim 0$
 - ▶ known vertex reco artifact
 - ▶ sometime the fit does not move from starting point

$\Delta T / \Delta z$ vs Truth

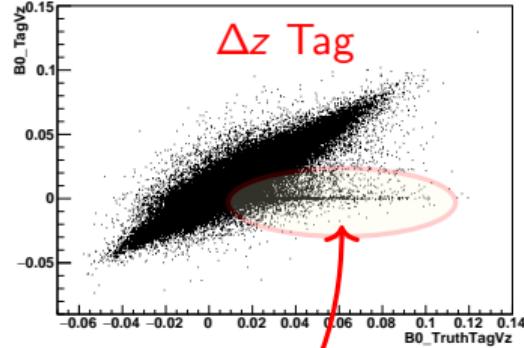

```
B0_DeltaT_B0_TruthDeltaT >0 && abs(B0_DeltaT_B0_TruthDeltaT) < 20 && abs(B0_DeltaT_B0_TruthDeltaT) > 10 && abs(B0_DeltaT_B0_TruthDeltaT) < 10
```

```
B0_Z_B0_TruthZ >0 && B0_isSignal && B0_TagVzTruth >0 && abs(B0_DeltaT) < 10 && abs(B0_TruthDeltaT) < 10
```

```
B0_TagVz_B0_TruthTagVz >0 && B0_isSignal && B0_TagVzTruth >0 && abs(B0_DeltaT) < 10 && abs(B0_TruthDeltaT) < 10
```

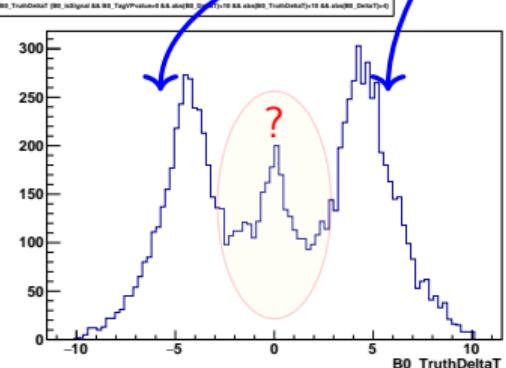

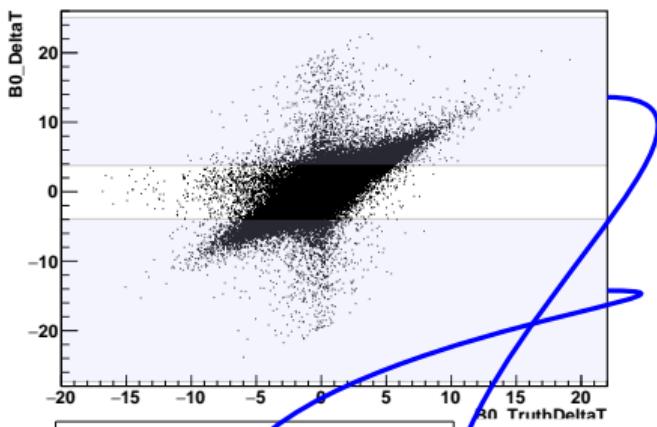

Structures visible:

- at $\Delta T_{\text{truth}} \sim 0$ and $\Delta T_{\text{truth}} < 0$
 - ▶ origin not so clear, not so visible in Δz signal
- at $z_{\text{reco}} \sim 0$
 - ▶ known vertex reco artifact
 - ▶ sometime the fit does not move from starting point

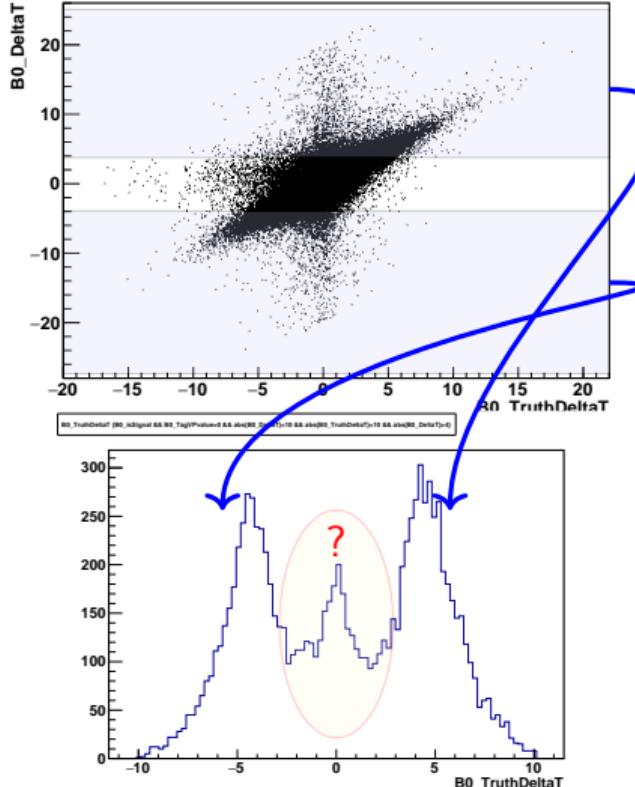

ΔT structures

Structure more visible if we look at ΔT_{truth} for tails of ΔT_{reco}

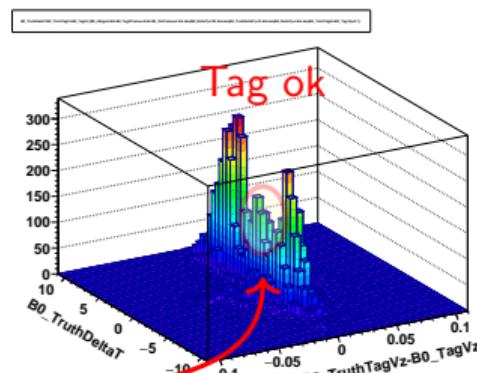

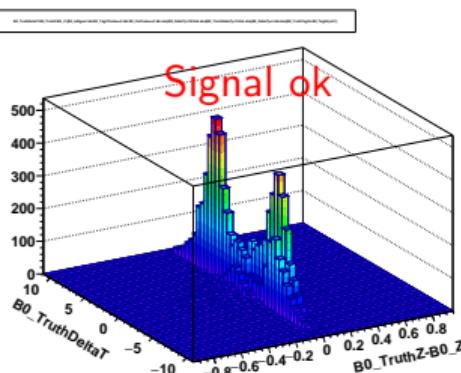

ΔT structures

Structure more visible if we look at ΔT_{truth} for tails of ΔT_{reco}

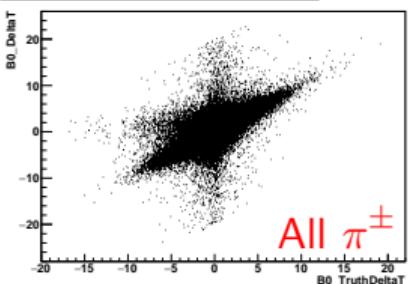

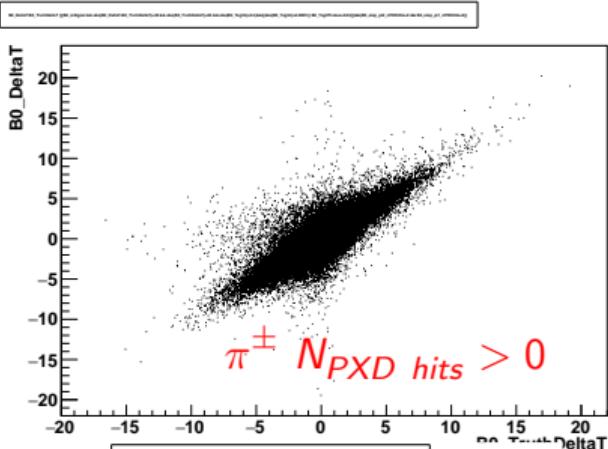

Look separately at Δz for signal and tag for tails in ΔT

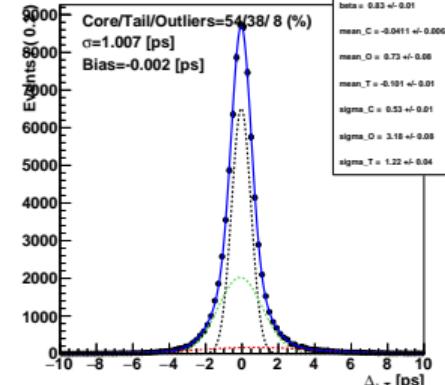

Sometime ΔT is wrong even if Δz_{tag} is correct.
Problem is on signal side

If we requires that π^\pm from η' has > 0 PXD hits

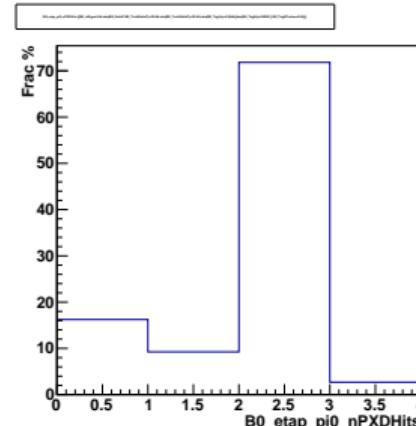

ΔT resolution improves (was 1.15 ps)

Time resolution

alpha = 0.54 +/- 0.02
 beta = 0.83 +/- 0.01
 mean_C = -0.0411 +/- 0.006
 mean_O = 0.73 +/- 0.08
 mean_T = -0.191 +/- 0.01
 sigma_C = 0.53 +/- 0.01
 sigma_O = 3.18 +/- 0.08
 sigma_T = 1.22 +/- 0.04

but > 15% of ϵ drop for each track!

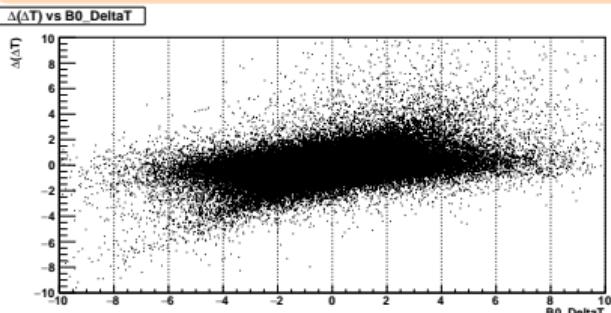

VXDTF1

VXDTF2

Channel	Overall reconstruction ϵ	PXD hit association ϵ	Overall reconstruction ϵ	PXD hit association ϵ
$\phi[K'K'] K_s[\pi'\pi']$	24.0%	68.6%	30.1%	82.0%
$\phi[\pi'\pi'\pi^0] K_s[\pi'\pi']$	18.1%	78.9%	22.0%	92.7%

No! Clear dependence on ΔT_{reco}

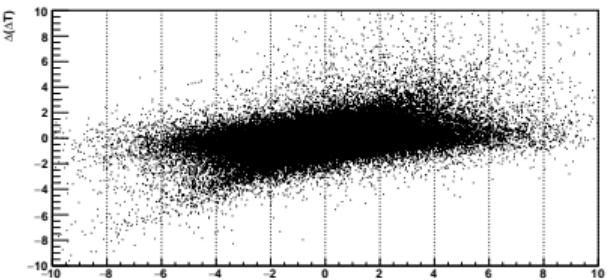

- Divide distribution in slices (10)
- fit each with a tri-gaussian

Is a single tri-gaussian enough to model the ΔT resolution?

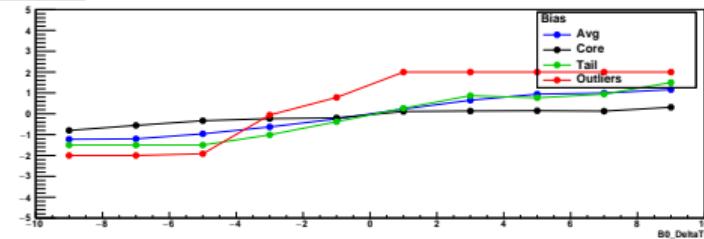

No! Clear dependence on ΔT_{reco}

$\Delta(\Delta T)$ vs $B_0 \cdot \Delta t$

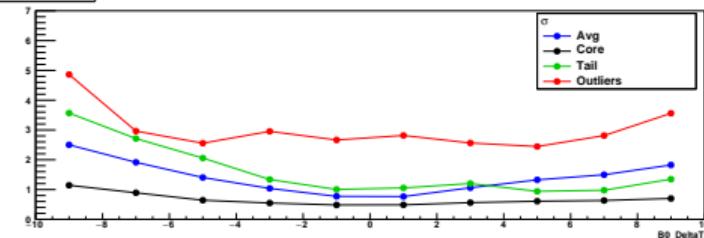

- Divide distribution in slices (10)
- fit each with a tri-gaussian
- right plot shows for (Core/Tail/Outliers/Avg):
 - ▶ biases
 - ▶ sigmas
 - ▶ fractions
- clear trend for biases and sigmas

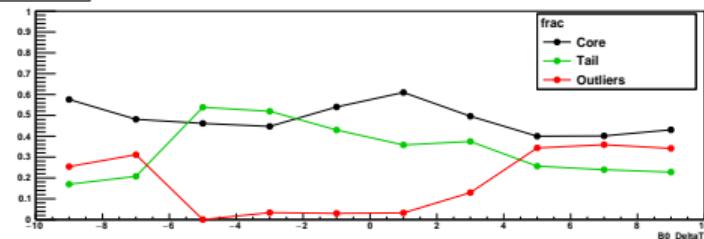

Bias vs $B_0 \cdot \Delta t$

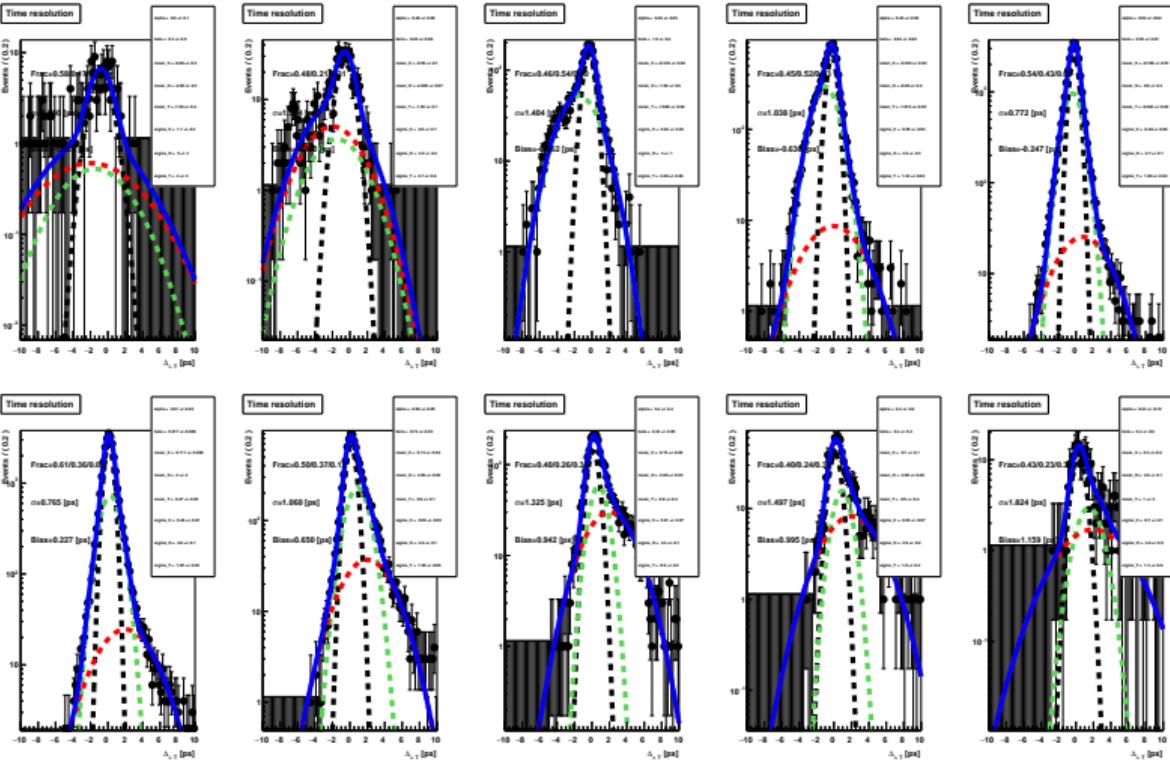

Sigma vs $B_0 \cdot \Delta t$

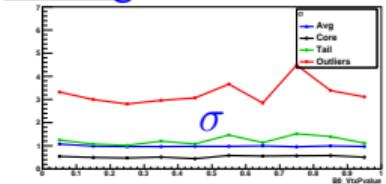

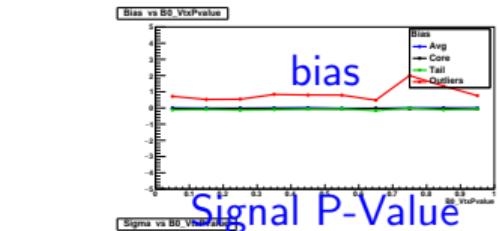

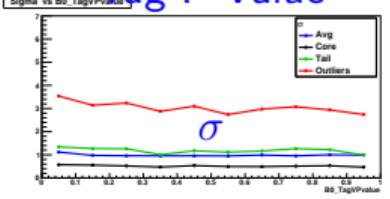

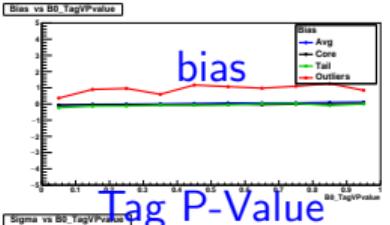

FracC vs $B_0 \cdot \Delta t$

$\Delta(\Delta T)$ vs $B0 \rightarrow \text{DeltaT}$: slices fit

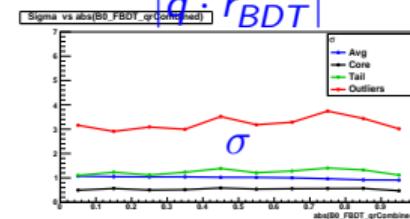

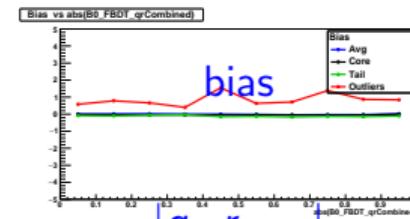

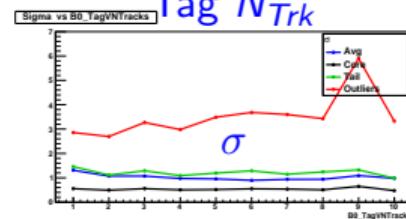

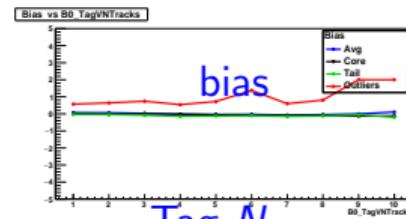

Other correlations?

- search for correlation with other variables:

- Tag/Signal Vertex P-value;
- Number of tracks used in Tag Vertex;
- Flavor Tagging output (á la BaBar);
- ...

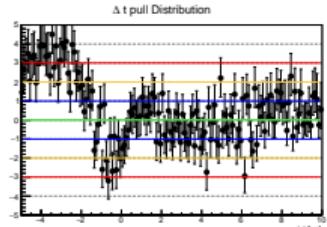

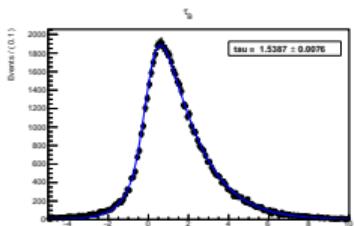

- nothing significant found

NB: Red is for outliers, always \sim negligible fraction

how to take use correlation between resolution parameters and $\Delta T_{reco(true)}$

- RooDecay can convolute exp. with gaussian resolution functions, also parametric
- nevertheless it fails if the parameters of the resolution are left as functions of ΔT
- eventually the whole function has been written down by hand and coded

- Fit to the reconstructed one sided ΔT distribution
- resolution parameters from simultaneous fit in ΔT_{true}
- result seem ok: $\tau_B = 1.539 \pm 0.008\dots$
- but a strong dependence on the tails and outliers components is observed

Still some work is needed for a deeper understanding

- ① tried modelling the resolution as a function of ΔT_{reco} or ΔT_{truth}
 - ▶ in principle the two approaches should be equivalent, but results differs
- ② how properly evaluate the ΔT resolution parameters
 - ▶ some parameters \sim constant (σ , fractions)
 - ▶ compute the functional dependence of bias: two approaches under study
 - ★ bin dataset wrt $\Delta T_{reco(true)}$ and perform independent
 - ★ simultaneous fit in those categories

resolution parameters vs ΔT_{reco}

- core and outlier params consistent between the two methods
- Not so for tail
- fraction of core component is consistent, larger difference in tail/outlier components

	fit in bins	simultaneous fit
μ_C [ps]	$0.09 \cdot \Delta T - 0.05$	$0.07 \cdot \Delta T - 0.06$
μ_T [ps]	$0.34 \cdot \Delta T - 0.04$	$0.72 \cdot \Delta T - 0.06$
μ_O [ps]	$0.57 \cdot \Delta T + 1.92$	$0.51 \cdot \Delta T + 0.8$
σ_C [ps]	0.55	0.60
σ_T [ps]	1.01	0.73
σ_O [ps]	3.00	2.54
f_C	0.70	0.73
f_T	0.27	0.20

Per event ΔT error

since some release, ΔT error is available *per event*

- computed propagating the signal/tag vertex uncert. from vertex fit taking into account all correlation
- Warning: bug present in `rel-00-09-xx` fixed in `rel-01-00-xx` and patched for this work

Strange peak structure in distribution: coming from Tag-Side vertex error

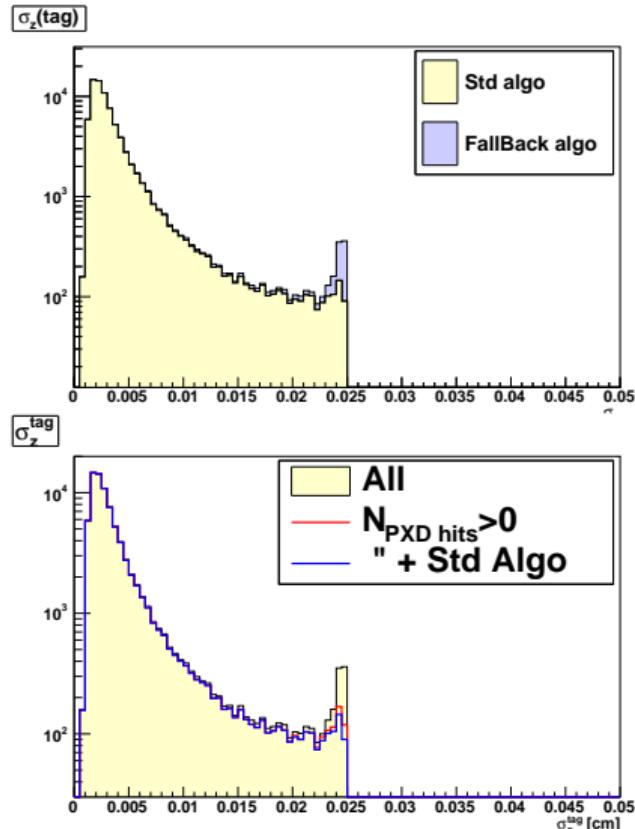

Tag vertex fit (breco) is performed using all RoE tracks

- iterative process, trying to add one track at a time;
 - possible to exclude tracks based on N_{PXD} hits
 - default no cut: $N_{PXD} \geq 0$
 - (only modifying the code)*
- it also perform a vertex constraint (iptube);
- if the constraint fails, a non constrained fit algo is used as a fall-back
 - (algo actually used not available at user level)*

peak for tag-side due fit with fall-back algo

requiring $N_{PXD} > 0$ also remove peak

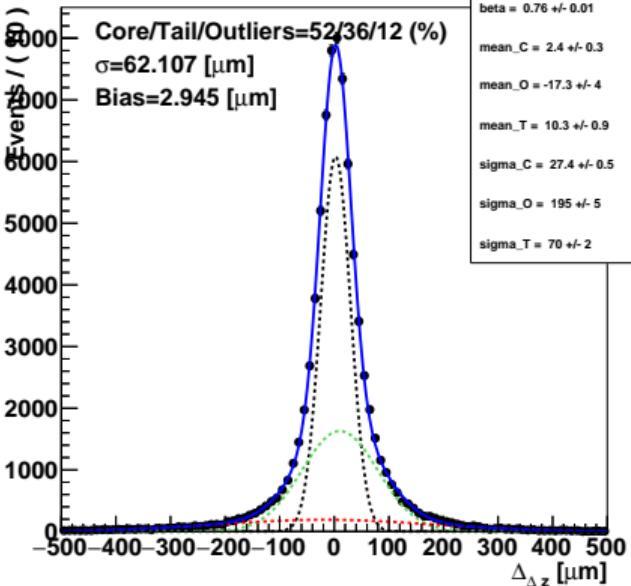

To be investigated by expert

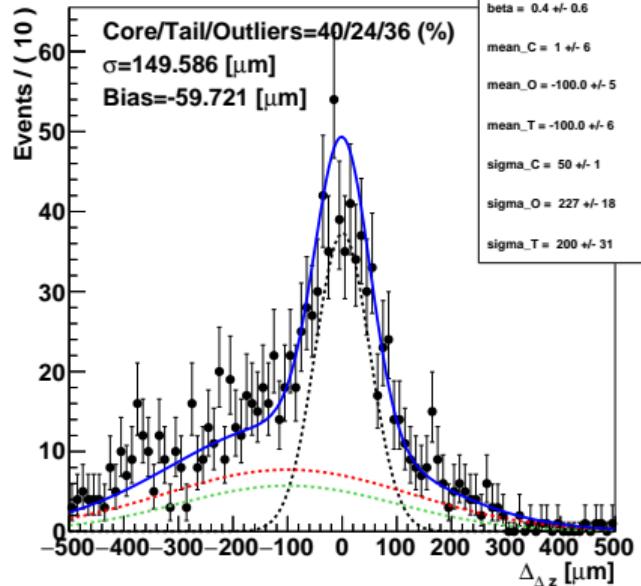

Impact on Tag-vertex resolution

Only 1.6% of events fitted with fall-back algo, but vertex resolution is significantly worse

Time resolution

Time resolution

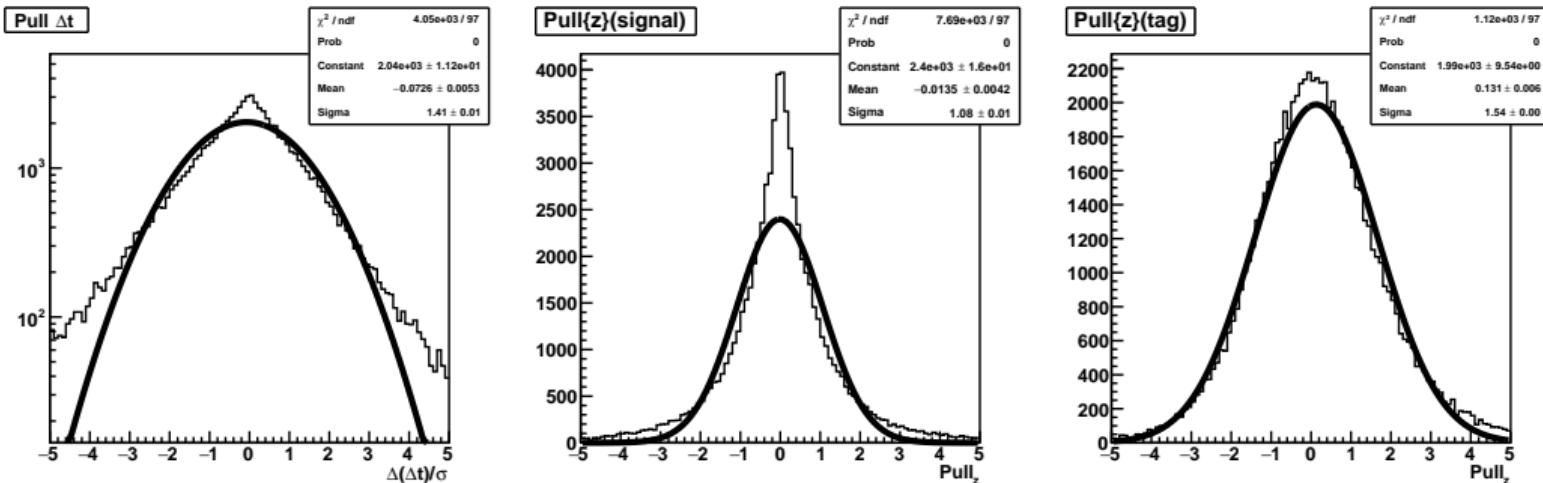

$\sigma_{\Delta T}$ in the τ_B fit?

Can we use the *per-event* $\sigma_{\Delta T}$ in the ML fit? Technically yes.

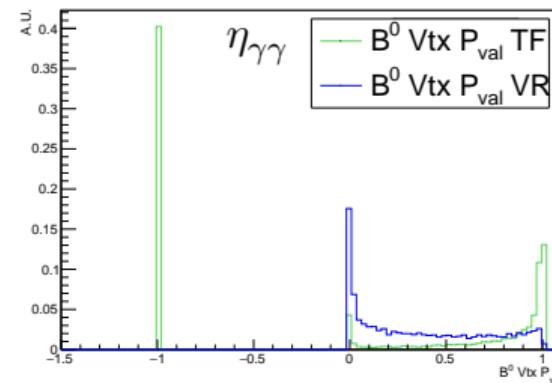

We need to check that the pull ($\Delta T/\sigma_{\Delta T}$) is reasonably gaussian ($mean = 0, \sigma = 1$)

- Not gaussian for ΔT ;
- $\sigma \sim 1$ for z_{signal} , but large tails;
- good gaussian for z_{tag} but $\sigma = 1.5$;

Started with default configuration (no constraints on intermediate state masses)

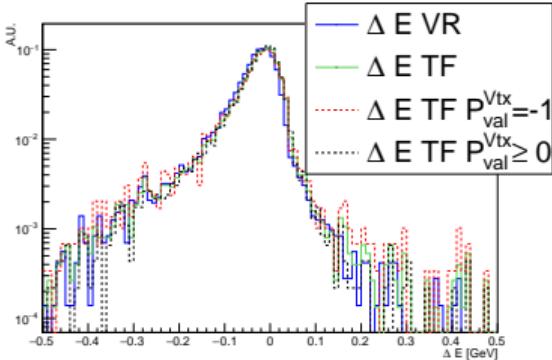

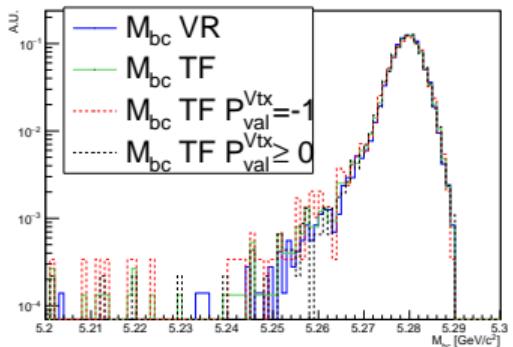

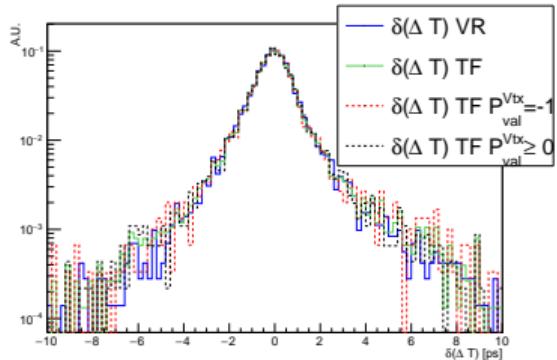

ε (%)	$\eta_{\gamma\gamma}$
VR all	36.4
VR B^0 _VtxPvalue > 0.001	31.7
TF all	39.4
TF B^0 _VtxPvalue > 0.001	22.1
head release: 20000 events	

Issue with efficiency

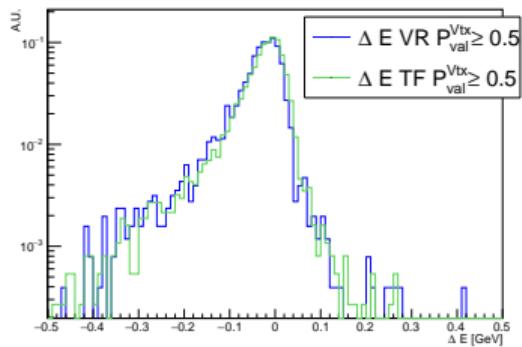

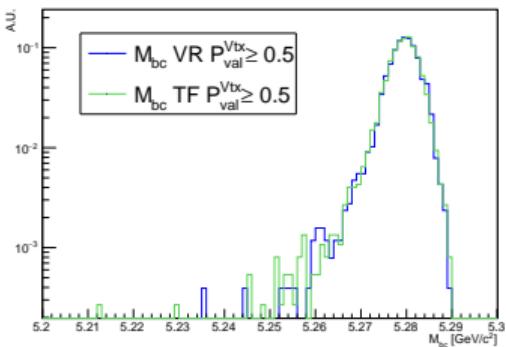

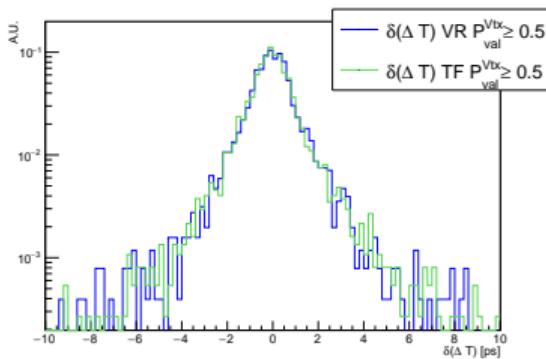

- The default cut on the Vtx P-value is 0.001 \Rightarrow efficiency drop $\sim 50\%$
- efficiency recovered (and slight improved) once all events are kept
- need to understand who are those guys with vtx P-val=-1: bug, wrong tool configuration
- had a look at some distributions but nothing relevant spotted (next slides)
- in contact with authors

ΔT resolution, M_{bc} , ΔE

- overall comparable performances with both Vertex Rave method (VR) and Tree Fitter (FT)
- no appreciable differences are observed between events with vxt $P_{val}=-1$ or ≥ 0
- a slight shift in ΔE is observed when using TF
- likely to be improved when intermediate masses constraints will be added

Looking at events with vtx $P_{val} \geq 0.5$

- also for good quality events comparable performances are observed with both Vertex Rave method (VR) and Tree Fitter (FT)
- likely to be improved when intermediate masses constraints will be added

Still work in progress, no conclusion yet: hopefully for next B2GM

- ΔT resolution has several structures related to reconstruction/vertexing
 - ▶ Some identified, some still unclear
 - ▶ need to test VXDTF2 reconstruction to see if improves PXD hits usage for prompt tracks
- τ_B fit with ΔT dependent resolution function tried
 - ▶ still technical difficulties
 - ▶ preliminary results promising
- per event $\sigma_{\Delta T}$ has still many issues, mostly on tag side
 - ▶ also pulls are not so good
 - ▶ will test anyway in the τ fit
- first test with TreeFitter
 - ▶ Issues with efficiency
 - ▶ vertex P-value interpretation
