

Year-long quasi-periodicities of gamma-ray blazars: a cautious approach

The background

Fermi was launched on June 2008:

- a natural product of such a mission is a large database of almost uninterrupted HE observations.
- Periodicities studies are then possible, at least for the brightest and persistent sources.
- No surprise then that claims for (hint of) periodicities have been reported for several blazars.

Periodicity in blazars. If true...

- it might be due to SBBH systems (e.g. Letto & Valtonen 1996; Graham et al. 2015);
- or to instabilities in the relativistic jet or in the accretion disk (e.g. Camenzind & Krockenberger 1992; Marscher 2014; Raseri et al. 2017).
- Not here to discuss the plausibility of these ideas, yet they are intriguing and worth some consideration.

The sample of analysed blazars

- 9 objects, chosen because possible periodicities in their Fermi light-curves have been reported (with various level of confidence) in the literature (e.g. Ackermann et al. 2015; Prokhorov & Moraghan 2017; Sandrinelli 2014, 2016a,b, 2017, 2018; Tavani et al. 2018; Zhang et al. 2014; Zhang et al. 2017);
- PG1553+113, PKS2155-304, BL Lac, PKS0301-243, 4C+01.28, 0716+714, PKS0805-077, PKS0537-304 and PKS2052-474
- This is, clearly, a highly biased sample.

Typical curves:

(Sandrinelli et al. 2018)

Time series

- Time series analysis is undoubtedly a very complex field. The availability of reliable and easy to use software tools might tend to hidden the real troubles.
- A few items, with no claim of completeness...
 - our theorems strictly hold for infinite, stationary, time-series;
 - if noise is structured (correlated, red, etc.) it must be properly modelled;
 - red-noise can mimic non-persistent periodical behaviours (e.g. Quinn & Hannan 2001; Rao 2016);
 - if sampling is uneven a large number of additional factors have to be considered (e.g. Vaughan 2012; Vio et al. 2013; Kelly et al. 2014; VanderPlas 2017; etc.).

Fermi temporal analysis

- Regular sampling (after rebinning):
 - analysis can be carried out at the Fourier frequencies;
 - powers form an orthonormal space;
 - We chose curves with 30 day binning.
- PDS are fit assuming a power-law shape for the noise with a proper (Whittle) likelihood and Leahy normalisation (Leahy et al. 1982; Barret & Vaughan 2012; Guídorzi et al. 2016).

$$S_{\text{PL}}(f) = Nf^{-\alpha} + B$$

$$S = -2 \ln \mathcal{L} = \nu \sum_{j=1}^{N-1} \left\{ \frac{I_j}{S_j} + \ln S_j + \left(\frac{2}{\nu} - 1 \right) \ln I_j + c(\nu) \right\}$$

Fermi temporal analysis (cont'd)

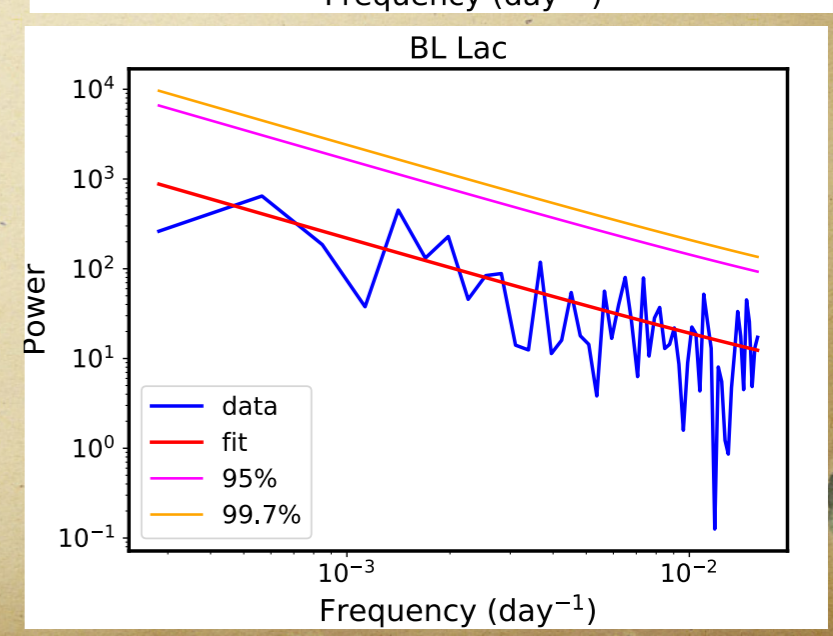

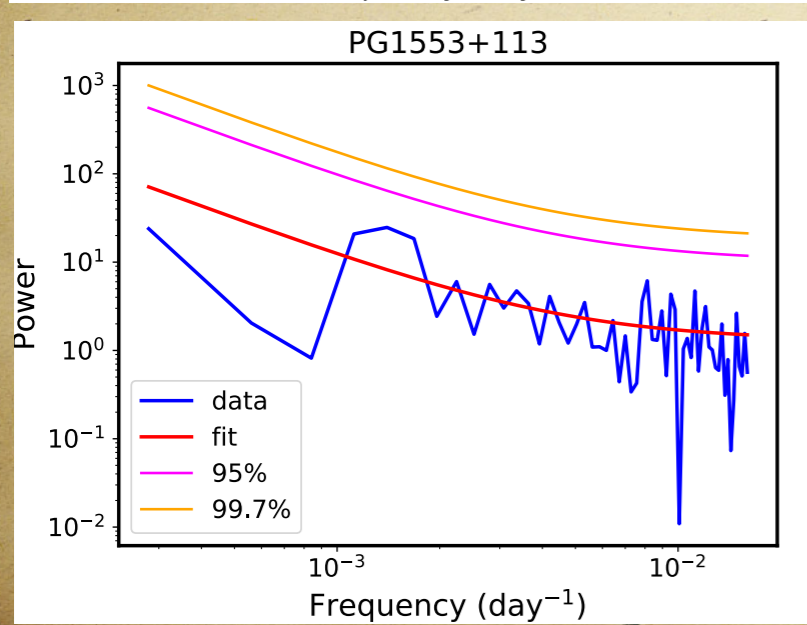

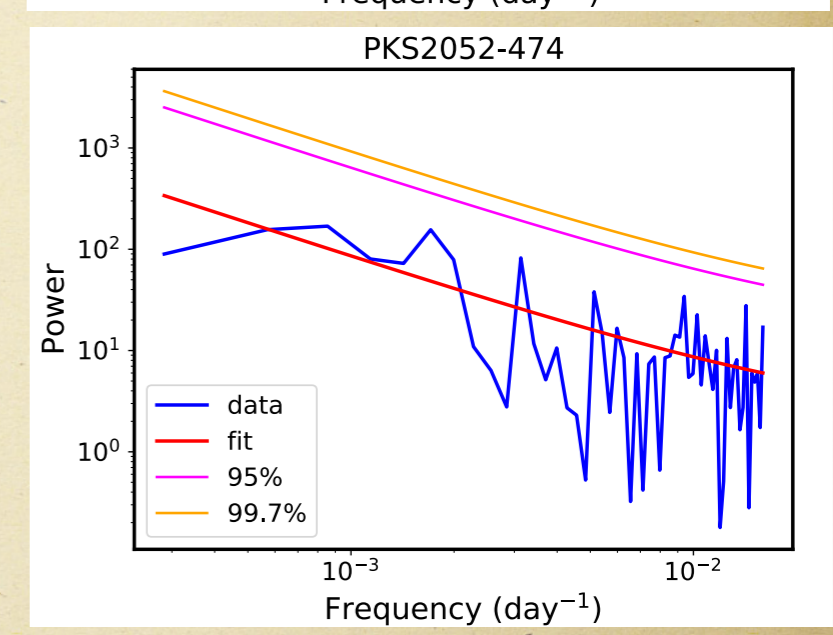

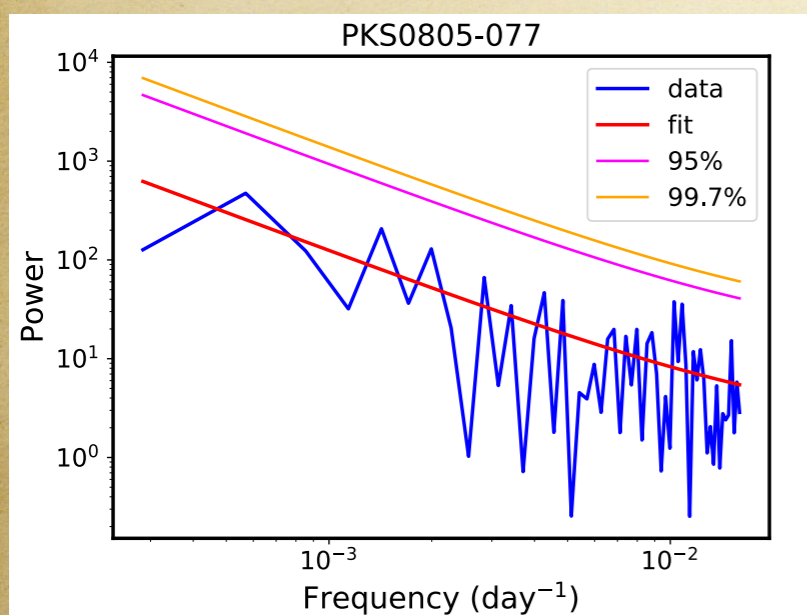

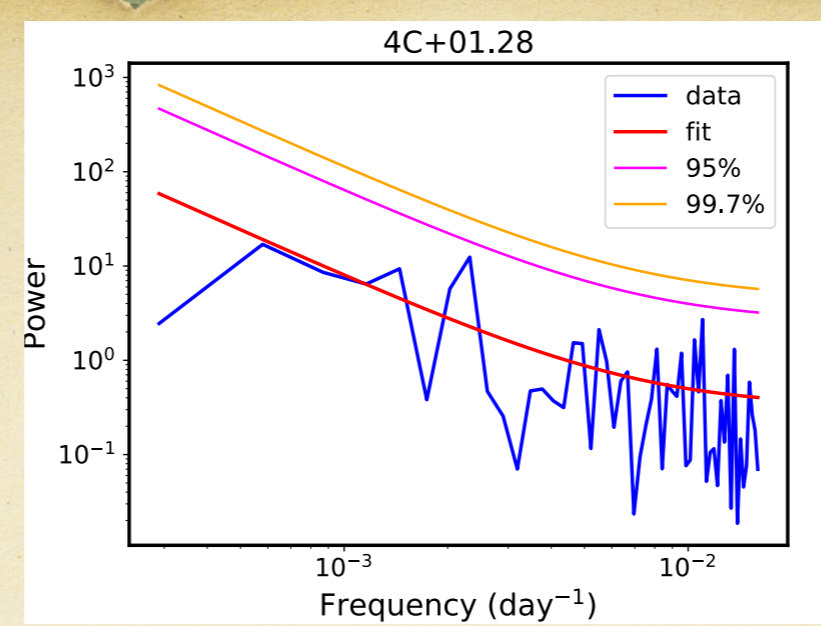

- Fully Bayesian analysis:
 - Jeffreys prior for normalisation, strictly positivity for the slope, and white noise in a Gaussian distribution centred on the expected value of 2 (e.g. Guidorzi 2011, 2016);
 - artificial PDS are generated by sampling the posterior distribution derived by affine-invariant Hamiltonian MCMC integration ("emcee" library);
 - PDS fit quality evaluated by posterior predictive assessment (Gelman et al. 1996);

Fermi temporal analysis (cont'd)

- Global significance curves are derived by the distribution of the “test” statistics $R = 2P/S$, where P are the simulated PDS, and S is the best-fit PDS (Vaughan 2010);
- The trial factor, i.e. the number of independent analysed frequencies, is intrinsically included in the analysis;
- The procedure has been developed mainly by: Vaughan 2010; Guidorzi 2011; Vaughan 2012; Barret & Vaughan 2012; Guidorzi et al. 2016.

Caveats and considerations

- Let's make the whole matter simple: all the analysed power spectra are consistent as just due to noise!
- In several cases reported in literature, only "hint of" periodicities are mentioned. No surprise nothing very meaningful is found.
- Let's not forget, anyway, that with long (quasi-)periodicities, the total duration of the Fermi monitoring makes possible to study only a few cycles.

Caveats and considerations (2)

- Yet, for PKS0537-441 and PKS2155-304 (and PG1553+113) it is still true that some interest is raised by the simultaneous presence of low-significance QPOs in multiple bands.
- A more technical point: Fourier analysis identifies sinusoidal possible periodicities. Analyses not assuming a specific functional form (e.g. non parametric) are possible, with pros and cons.
