

Non-extensive solution to the cosmological lithium problem

Monday, 25 June 2018 16:00 (15 minutes)

The disagreement of the predicted abundance of primordial ${}^7\text{Li}$ with the observed abundance is a longstanding problem in Big Bang Nucleosynthesis theory[1, 2]. Solutions to this problem using conventional astrophysics and nuclear physics have not been successful over the past few decades[3]. We have investigated the impact on BBN predictions of adopting a generalized distribution called Tsallis distribution to describe the velocities of nucleons. We find excellent agreement between predicted and observed primordial abundances of D, ${}^4\text{He}$, and ${}^7\text{Li}$ for $1.069 \leq q \leq 1.082$, suggesting a possible new solution to the cosmological lithium problem[4].
