# Outline

1. Twisted photons: generation, applications, observations.
2. Problem statement and results.
4. Undulators:
   - Dipole regime.
   - Wiggler.
5. Conclusion.
Twisted photons: generation, applications, observations

Definition
The twisted photons are the states of a free electromagnetic field with the definite energy $k_0$, the longitudinal projection of momentum $k_3$, the projection of the total angular momentum $m$, and the helicity $s$.

Generation
1. Spatial light modulators and digital micro-mirror devices (optical range and below) [e.g., A. Jesacher et al., Opt. Express 15, 5801 (2007)].
2. Spiral phase plates and diffraction gratings with $\ell$-pronged forks dislocations (x-ray range and below) [M.W. Beijersbergen et al., Opt. Commun. 112, 321 (1994); V.Y. Bazhenov et al., JETP Lett. 52, 429 (1990)].
Twisted photons: generation, applications, observations

Applications

1. High-density information transfer.
2. Manipulation of the rotational degrees of freedom of irradiated objects: microstructures, molecules, atoms, nuclei, hadrons.
3. High-contrast microscopy.
4. Particle trapping and optical tweezers.

Observation of twisted photons at a single-photon level

Problem statement

Issues we are going to address

- To obtain the general formula for the radiation probability of twisted photons by classical currents.
- To develop theory of generation of twisted photons by undulators.
- To find the IR asymptotics of radiation of twisted photons. The IR asymptotics of radiation of photons is universal for any QED process [F. Bloch, A. Nordsieck, Phys. Rev. 52, 54 (1937) and, e.g., S. Weinberg, Phys. Rev. 140, B 516 (1965)].
- To find the selection rules and symmetry properties of radiation and absorption probabilities of twisted photons.
Outcomes

Results

1. The general formula for the probability of radiation of a twisted photon by a classical current is derived.

2. The general theory of generation of twisted photons by undulators is developed.

3. The explicit formulas for the average number of twisted photons generated by undulators in both dipole and wiggler regimes are obtained.

4. The exact formula for the radiation probability of twisted photons in the far infrared is obtained.

5. The main characteristics of the radiation twist – the differential asymmetry, the average projection of the total angular momentum of radiation, and the projection of the total angular momentum per photon – are found.

6. The main properties of the radiation probability of twisted photons by ultrarelativistic charged particles are established. In particular, the probability of radiation of twisted photons has a sharp peak near $n_\perp \approx \beta_\perp$, where $n_\perp = k_\perp / k_0$ and $k_\perp := \sqrt{k_0^2 - k_3^2}$. 
Results (continuation)

Symmetries and selection rules:

- For the forward radiation of an ideal right-handed helical undulator the harmonic number $n$ of a twisted photon coincides with its projection of the total angular momentum $m$. As for the ideal left-handed helical undulator, $m = -n$.

- The forward radiation of twisted photons by a planar undulator obeys the selection rule that $n + m$ is an even number.

- The average number of twisted photons produced by the undulator and detected off the undulator axis is a periodic function of $m$ in a certain spectral band of the quantum number $m$.

- The symmetry property of the average number of twisted photons produced by a charged particle moving along a planar trajectory is found in the case when the detector axis lies in the orbit plane.

- The general symmetry property of the average number of twisted photons produced in any QED process in the far infrared is established:

\[
dP(s, m, k_3, k_\perp) = dP(-s, -m, k_3, k_\perp).
\]
Selection rules for symmetric sources:

- If the current density $j^i(t, x)$ is invariant under the rotation by an angle of $2\pi/r$, $r \in \mathbb{N}$, around the detector axis for all $t$, then

$$dP(s, m, k_3, k_\perp) = 0, \quad m \neq lr, \quad l \in \mathbb{Z}. \quad (2)$$

- If the trajectories of identical charged particles are obtained from one trajectory by the rotation by an angle of $\varphi_k$, the translation along the detector axis by $x^k_3$, and the translation in time $x^k_0$, where

$$\varphi_k = \frac{2\pi k}{r}, \quad x^k_3 = \frac{\lambda_0}{2\pi} \varphi_k, \quad x^k_0 = \frac{\lambda_0}{2\pi \beta_{||}} \varphi_k, \quad k = \overline{1, r}, \quad (3)$$

and $\lambda_0$ and $\beta_{||}$ are some fixed parameters, then there is the selection rule

$$m = \text{sgn}(\lambda_0)n + lr, \quad k_0 = k_0^n := \frac{2\pi n}{|\lambda_0| (\beta_{||}^{-1} - n_3)}, \quad n \in \mathbb{N}, \quad l \in \mathbb{Z}, \quad (4)$$

$n_3 := k_3/k_0$, at the sharp maxima of radiation probability of twisted photons.

- If the initial and final velocities and the detector axis lie in one plane, the initial and final energies and the velocity projections to the detector axis are the same, then $m$ is an odd number in the far infrared.
Radiation of twisted photons by classical currents

Basis

\[ \mathbf{e}_\pm := \mathbf{e}_1 \pm i \mathbf{e}_2. \quad (5) \]

\( \{\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3\} \) is a right-handed orthonormal triple.

\( \mathbf{e}_3 \) is directed along the detector axis.

Vector decomposition

\[ \mathbf{x} = \frac{1}{2}(x_- \mathbf{e}_+ + x_+ \mathbf{e}_-) + x_3 \mathbf{e}_3. \quad (6) \]

\( x_\pm = (\mathbf{x}, \mathbf{e}_\pm) \) and \( x_3 = (\mathbf{x}, \mathbf{e}_3) \).

Process of radiation of photons

\[ 0 \rightarrow \gamma_\alpha + \mathbf{X}. \quad (7) \]

0 is the vacuum state.

\( \gamma_\alpha \) is the photon in the state \( \alpha \) recorded by the detector.

\( \mathbf{X} \) is for the other created photons.

Probability of the inclusive process (7)

\[ w_{incl}(\alpha; 0) = 1 - e^{-n(\alpha; 0)} \approx n(\alpha; 0). \quad (8) \]

\( n(\alpha; 0) \) is the average number of photons in the state \( \alpha \) created by the current \( j_\mu(x) \).
Radiation of twisted photons by classical currents

Density of the average number of twisted photons created by the current of \( N \) particles

\[
dP(s, m, k_3, k_\perp) = \left| \sum_{l=1}^N e_l \int d\tau_l e^{-i[k_0 x_l^0(\tau_l) - k_3 x_l^3(\tau_l)]} \left\{ \frac{1}{2} \left[ \dot{x}_l^+(\tau_l) a_-(s, m, k_3, k_\perp; x_l(\tau_l)) + \dot{x}_l^-(\tau_l) a_+(s, m, k_3, k_\perp; x_l(\tau_l)) \right] + \dot{x}_l^3(\tau_l) a_3(m, k_\perp; x_l(\tau_l)) \right\}^2 \frac{(k_\perp^2)^3}{4k_0^3} \frac{dk_3 dk_\perp}{2\pi^2}. \tag{9}
\]

\( k_0 \) is the photon energy. \( k_\perp := \sqrt{k_0^2 - k_3^2} \).

\( s = \pm 1 \) is the photon helicity.

\( m \in \mathbb{Z} \) is the projection of the total angular momentum of a photon onto the detector axis. The origin of the reference frame is taken on the line passing through the detector axis.

Mode functions
[e.g., R. Jáuregui et al., Phys. Rev. A 71, 033411 (2005)]

\[
a_3(m, k_\perp; x) = \frac{x_m^2}{x_-^m/2} J_m(k_\perp x_+^{1/2} x_-^{1/2}) =: j_m(k_\perp x_+, k_\perp x_-),
\]

\[
a_\pm(s, m, k_3, k_\perp; x) = \frac{i k_\perp}{s k_0 \pm k_3} j_{m\pm 1}(k_\perp x_+, k_\perp x_-).
\]

P.O. Kazinski (TSU)
Characteristics of radiation with angular momentum

Differential asymmetry

\[ A(s, m, k_3, k_0) := \frac{dP(s, m, k_3, k_0) - dP(s, -m, k_3, k_0)}{dP(s, m, k_3, k_0) + dP(s, -m, k_3, k_0)}. \]  \hspace{1cm} (11)

Projection of the total angular momentum per photon

\[ \ell(s, k_3, k_0) := \frac{dJ_3(s, k_3, k_0)}{dP(s, k_3, k_0)} \] \hspace{1cm} (12)

\[ dJ_3(s, k_3, k_0) := \sum_{m=-\infty}^{\infty} m dP(s, m, k_3, k_0), \quad dP(s, k_3, k_0) = \sum_{m=-\infty}^{\infty} dP(s, m, k_3, k_0). \] \hspace{1cm} (13)

Integrated projection of the total angular momentum per photon

\[ \ell(s, k_0) := \frac{dJ_3(s, k_0)}{dP(s, k_0)}, \] \hspace{1cm}

\[ dJ_3(s, k_0) = \int_0^{k_0} dk_3 \frac{dJ_3(s, k_3, k_0)}{dk_3}, \quad dP(s, k_0) = \int_0^{k_0} dk_3 \frac{dP(s, k_3, k_0)}{dk_3}. \] \hspace{1cm} (14)
Undulators: Dipole regime for a planar undulator at the first harmonic

Figure: Trajectory: $a_z = a_y = 0$, $a_x = K \lambda_0 / (\sqrt{2} \pi \gamma)$, where $K = 0.03$ is the undulator strength parameter, $\lambda_0 = 1 \text{ cm}$ is the length of the undulator section, and $\gamma = 10^3$ is the Lorentz-factor of the electron. The number of undulator sections $N = 40$. The energy of photons is measured in the units of the electron rest energy $0.511 \text{ MeV}$ and $n_\perp := k_\perp / k_0$. (a) The distribution over $m$, the asymmetry, and the angular momentum projection per photon. The period of oscillations $T_m = 4$. 

\[
\ell = 0.23, \; m_{\max} = 26 \\
n_\perp = 1/\gamma, \; k_0 = 2.76 \times 10^{-4}, \; s = 1 \\
\theta = 1/5\gamma, \; \phi = \pi/10
\]
Figure: (b) The density of the average number of twisted photons against $k_0$ for different observation angles. The dashed vertical line in the inset depicts the photon energy used in the plot (a) on the previous slide. (c) The density of the average number of twisted photons against $m$ at the left and right peaks appearing in the distribution over the photon energy for $\theta = 1/(5\gamma)$ (see the inset in the plot (b)). The average number of photons obeys the symmetry relation (1).
Figure: Trajectory: $K = 4.6 \times 10^{-3}$ is the undulator strength parameter, $\lambda_0 = 1$ cm is the length of the undulator section, and $\gamma = 10^3$ is the Lorentz-factor of the electron. The number of the undulator sections $N = 40$. The energy of photons is measured in the units of the electron rest energy 0.511 MeV. (a) The distribution over $m$, the asymmetry, and the angular momentum projection per photon. The period of oscillations $T_m = 5$. 

\[ \ell = 0.93, m_{\text{max}} = 27 \]
\[ n_\perp = 1/\gamma, k_0 = 2.83 \times 10^{-4}, s = 1 \]
\[ \theta = 1/5 \gamma, \phi = \pi/10 \]
Figure: (b) The density of the average number of twisted photons against $k_0$ for different observation angles. The dashed vertical line in the inset depicts the photon energy used in the plot (a) on the previous slide. (c) The density of the average number of twisted photons against $m$ at the left and right peaks appearing in the distribution over the photon energy for $\theta = 1/(5\gamma)$ (see the inset in the plot (b)).
Figure: The distribution over $m$. The forward radiation of the planar undulator obeys the symmetry relation (1) and the selection rule $m + n$ is an even number. The forward radiation of the right-handed helical undulator obeys the rule $m = n$. The insets (a), (b), (c) are for the planar undulator, and (d) is for the helical one. The trajectories of the electron are the same as on the previous slides. The small contribution at $m = -1$ for the helical undulator is a consequence of deviation of the trajectory from an ideal right-handed helix.
Figure: Trajectory: $K = 4$, $\omega = 2\pi \beta_{||}/\lambda_0$, where $\lambda_0 = 1$ cm, $\gamma = 10^3$, and $N = 40$. (a) The distribution over $m$, the asymmetry, and the angular momentum projection per photon. The period of oscillations $T_m = 4$. 

\[ \ell = -4.08, \ n = 5 \]

\[ n_\perp = K/\gamma, \ k_0 = 7.6 \times 10^{-5}, \ s = 1 \]

\[ \delta = 1/5\gamma, \ \alpha = 0 \]
**Figure:** (b) The density of the average number of twisted photons against $k_0$ for different observation angles. The dashed vertical line in the inset depicts the photon energy used in the plot (a) on the previous slide. (c) The density of the average number of twisted photons against $m$ at the left and right peaks appearing in the distribution over the photon energy for $\theta = 1/(5\gamma)$ (see the inset in the plot (b)). As long as the observation angle $\alpha = 0$, the distributions over $m$ have the symmetry property (1).
Wigglers: Helical wiggler at the fifth harmonic

Figure: Trajectory: \( K = 4, \omega = 2\pi\beta_{||}/\lambda_0 \), where \( \lambda_0 = 1 \) cm, \( \gamma = 10^3 \), and \( N = 40 \). (a) The distribution over \( m \), the asymmetry, and the angular momentum projection per photon. The period of oscillations \( T_m = 4 \).
Figure: (b) The density of the average number of twisted photons against $k_0$ for different observation angles. The dashed vertical line in the inset depicts the photon energy used in the plot (a) on the previous slide. (c) The density of the average number of twisted photons against $m$ at the left and right peaks appearing in the distribution over the photon energy for $\theta = 1/(5\gamma)$ (see the inset in the plot (b)).
Figure: The forward radiation of the planar undulator obeys the symmetry relation (1) and the selection rule that $m + n$ is an even number. The forward radiation of the right-handed helical undulator obeys the rule $m = n$. The insets (a), (b), (c) are for the planar wiggler, and (d) is for the helical one. The trajectories of the electron are the same as on the previous slides.
The theory of radiation of twisted photons by classical currents is constructed.

The undulator radiation is studied in detail.

The IR asymptotics is investigated.

Several selection rules and symmetries for the radiation probability of twisted photons are established.
