

Light Dark Matter

AD Polosa

Cosmic visions report 2017: 1707.04591

$$\frac{d}{dt} m(t) a^3(t) = - \left[m a^3 \cdot m \langle v \sigma \rangle_T - m_{EQ} a^3 \cdot m \langle v \sigma \rangle_T \right]$$

← →

$$\begin{cases} m(t_1) a(t_1) \neq 0 \\ \text{with } t_1 \rightarrow \infty \end{cases}$$

$$\rho_\chi(\text{today}) \approx 2m_\chi \cdot 6B^{-0.95} (k_B T_0)^3$$

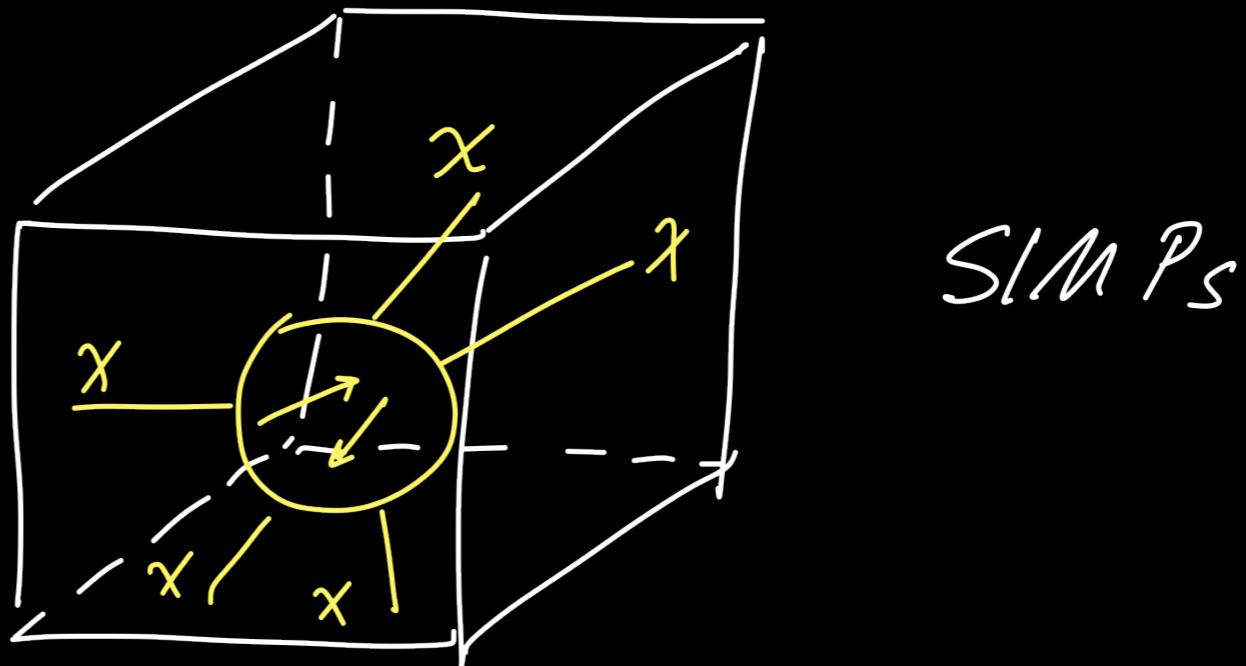

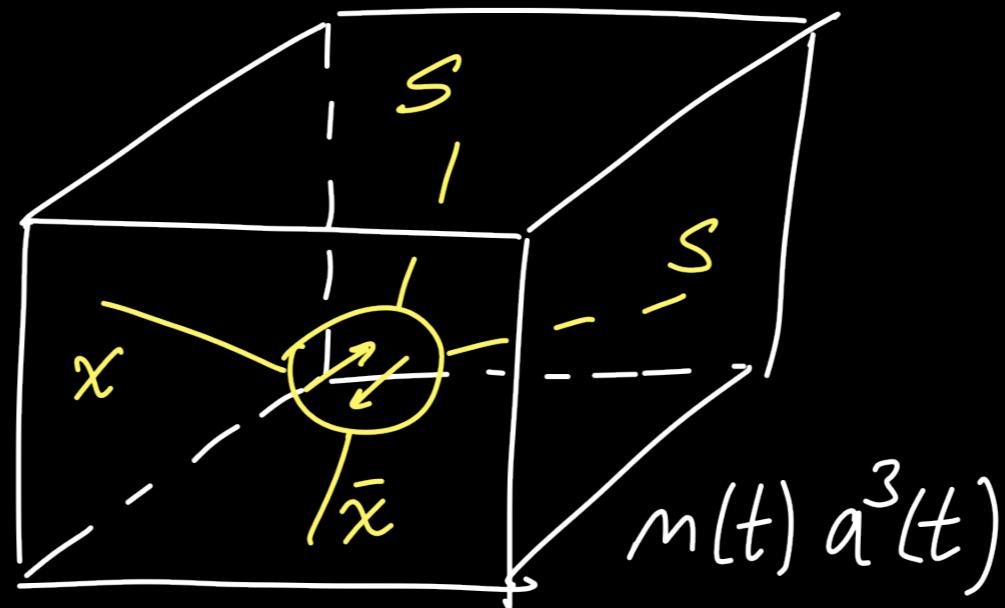

$$B = \sqrt{\frac{45}{4\pi^3 G_N N}} \langle \sigma v \rangle m_\chi$$

$$\Omega_\chi = \frac{8\pi G_N}{3H_0^2} \rho_\chi \simeq \mathcal{R}_M$$

$$\langle \sigma v \rangle_T = G_F^2 m_\chi^2 \frac{F}{2\pi} \quad (\underline{WIMP})$$

$$m_\chi \simeq 3.7 \left(\frac{N}{F} \right)^{1/2} (52_m h)^{-1/2} \text{GeV}$$

$$m_\chi \simeq 10 \text{ GeV} \quad \text{with } F = 1$$

Dark pions.

$$100 < m_\pi < 300 \text{ MeV}$$

[Murayama et al.]

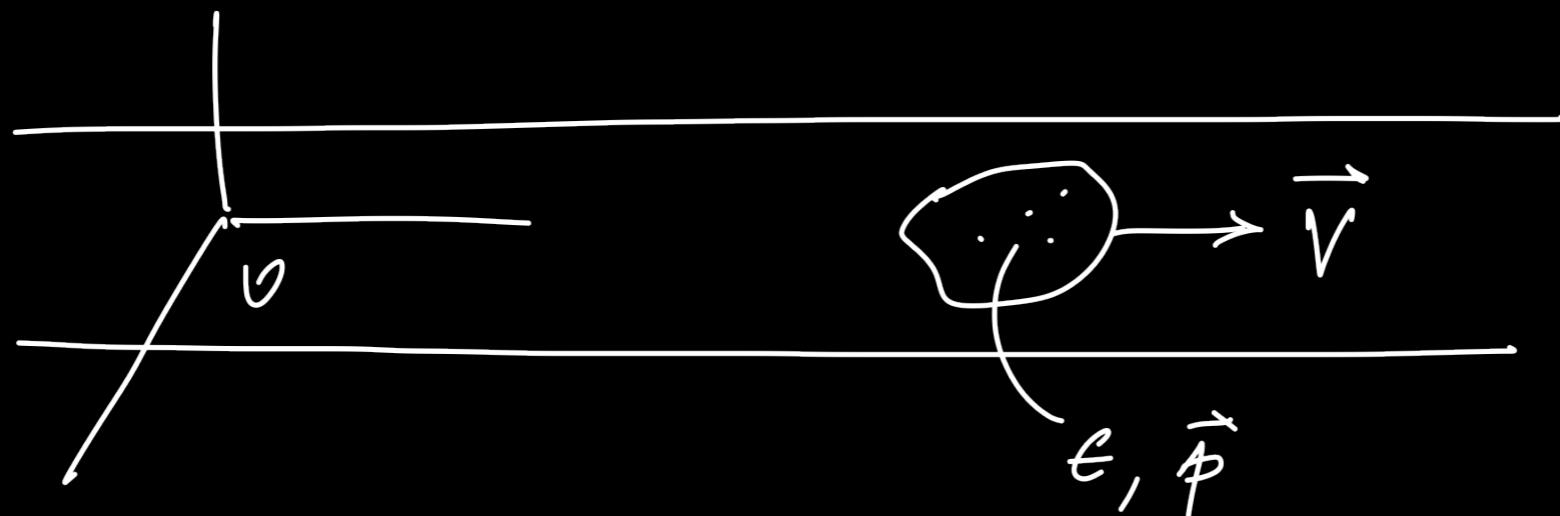

WIMPS : look for nuclear recoils

SIMPS : look for e^- recoils

CRYSTALS, GAS, LIQUIDS, SEMICONDUCTORS

SUPERCONDUCTORS...

SUPERFLUIDS!

wrt \mathcal{O} : $\Delta E = \epsilon + \vec{p} \cdot \vec{V}$

$$\Delta E < 0$$

$$\epsilon - p \cdot V < 0$$

$$V > \frac{\epsilon}{p}$$

If $V < \frac{\epsilon}{p}$ no excitations get produced

$$V < \frac{\epsilon}{p}$$

let

$$\epsilon = \frac{p^2}{2m\star}$$

$$V > \frac{\epsilon}{p} \Rightarrow V > \frac{p}{2m\star} > 0$$

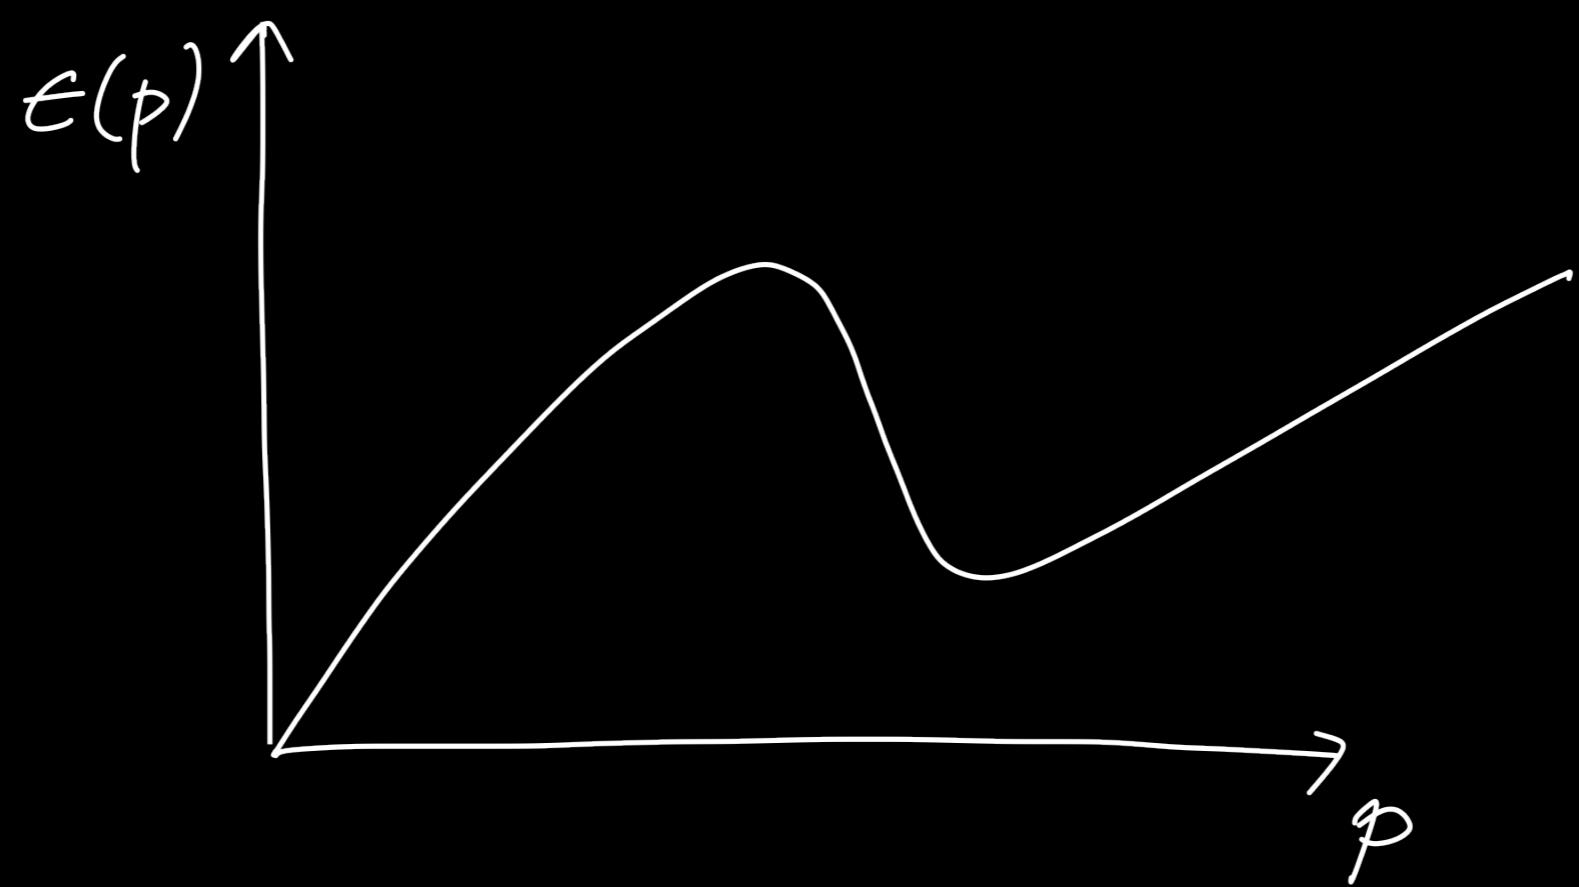

Super fluidity does not exist.

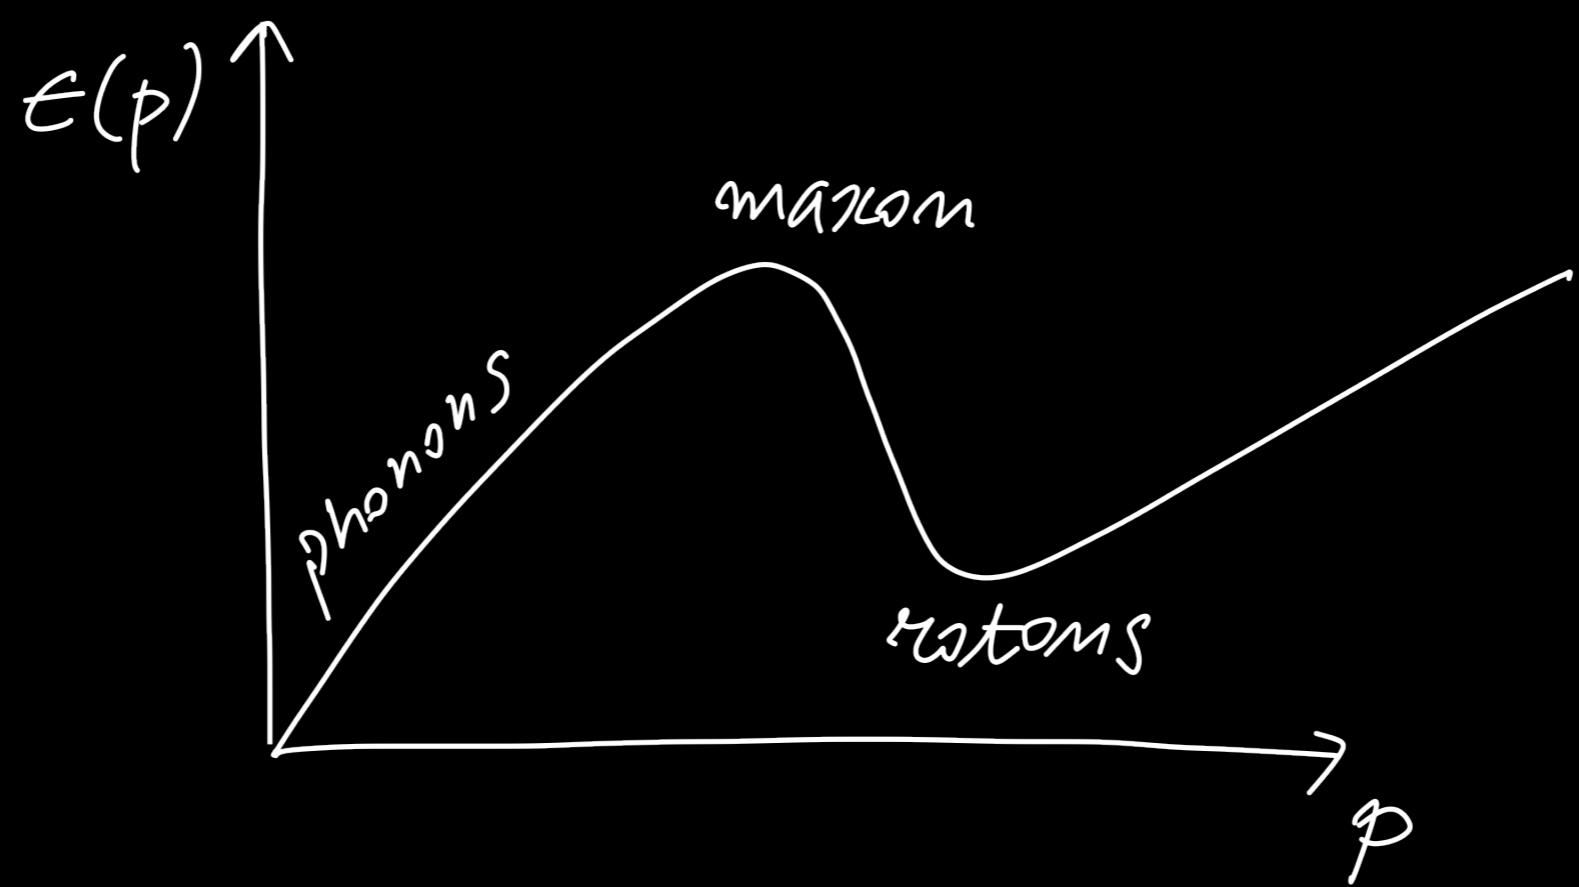

let

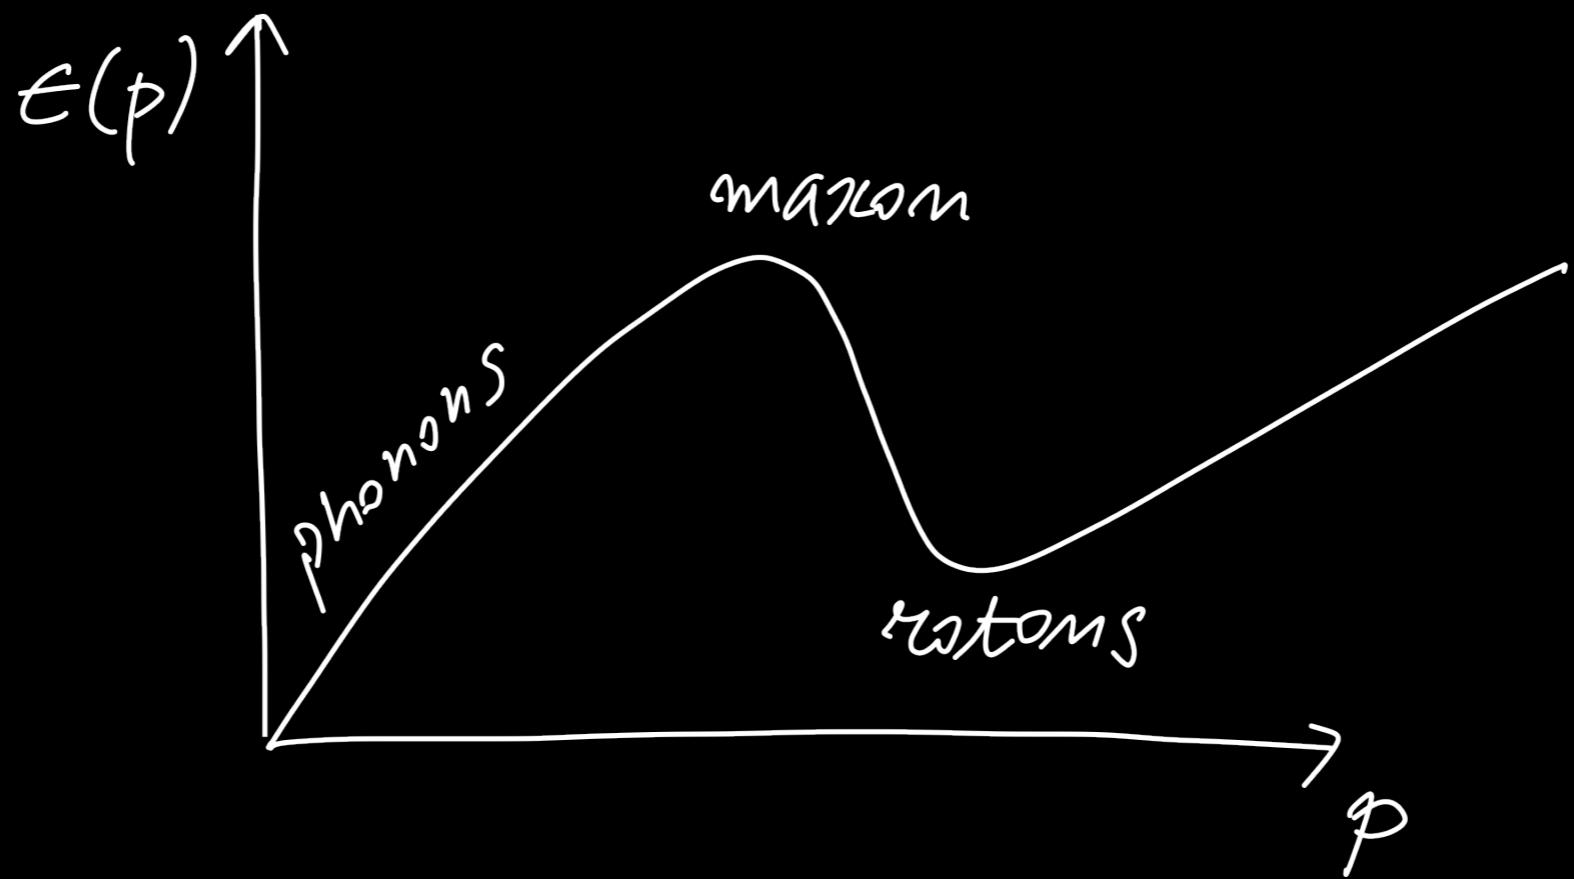

$$\epsilon = c_s p$$

We have superfluidity for

$$\epsilon < c_s$$

$$\epsilon(p) \approx \Delta + \frac{1}{2m^*} (p - p_0)^2$$

$$\Delta \simeq 0.8 \text{ meV}$$

$$p_0 \simeq 3.94 \text{ keV}$$

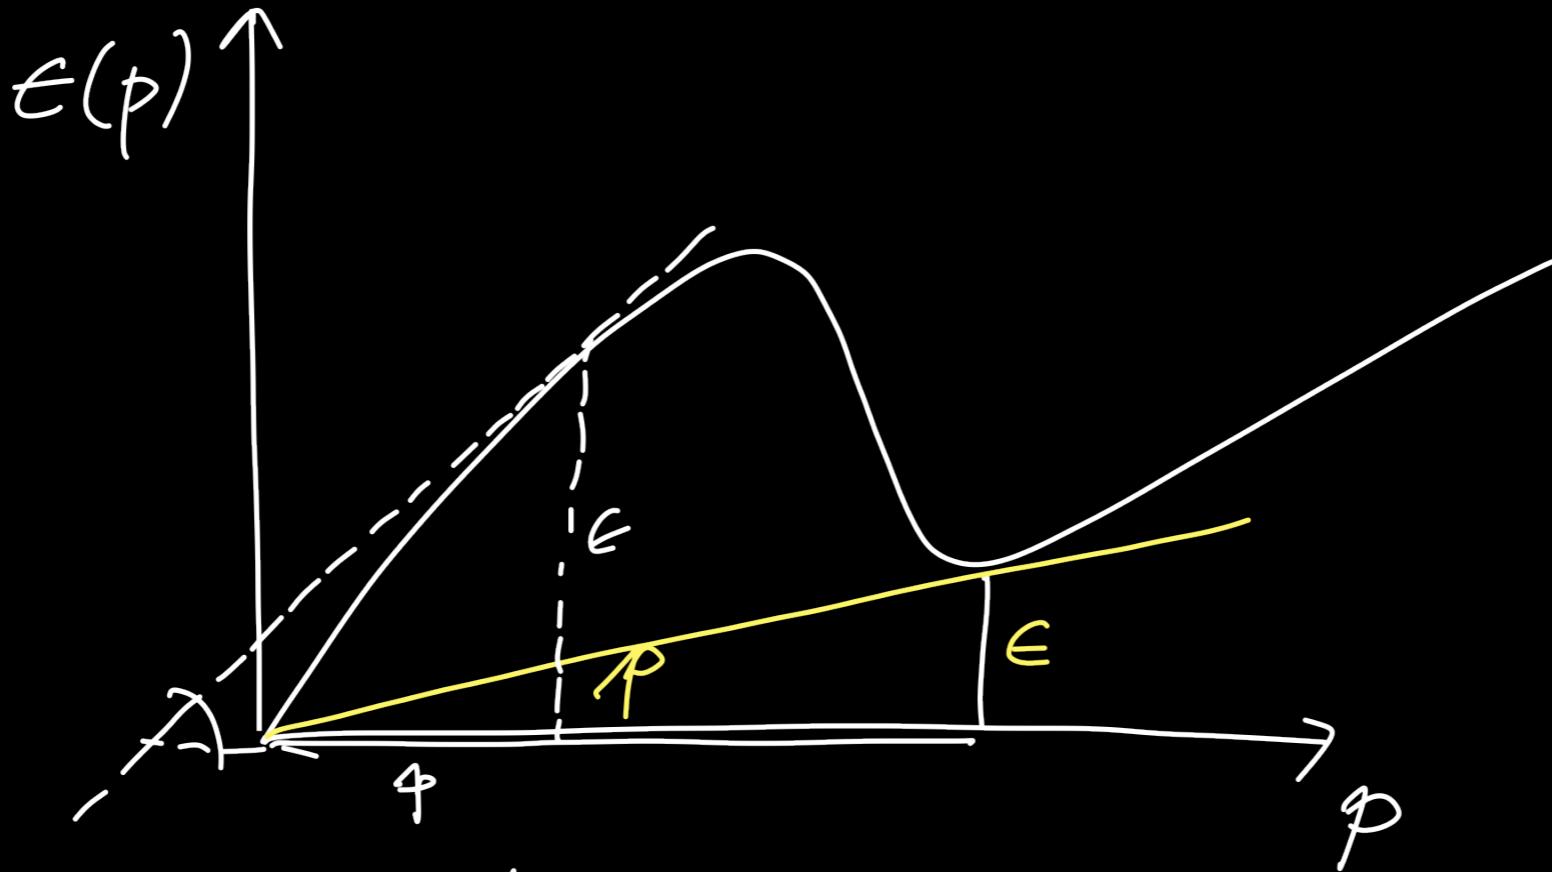

$$m^* \simeq 0.16 m_{He}^4$$

$$V > \frac{\epsilon}{p} > \min \frac{\epsilon}{p}$$

The minimum is found for

$$\frac{\partial \epsilon}{\partial p} = \frac{\epsilon}{p}$$

$$\nabla > \frac{\epsilon}{p} > \min \frac{\epsilon}{p}$$

The minimum is found for

$$\frac{\partial \epsilon}{\partial p} = \frac{\epsilon}{p}$$

For all other points on the left

$$\epsilon' > \epsilon/p$$

An excitation in the moving volume of liquid has velocity

$$v_g = \frac{\partial E}{\partial p} \quad (\text{direction opposite to } \vec{V})$$

which in the O frame reads

$$v = V - \epsilon'$$

$$> V - \frac{E}{P}$$

> 0 — in the direction of \vec{V}

but "lagging" behind.

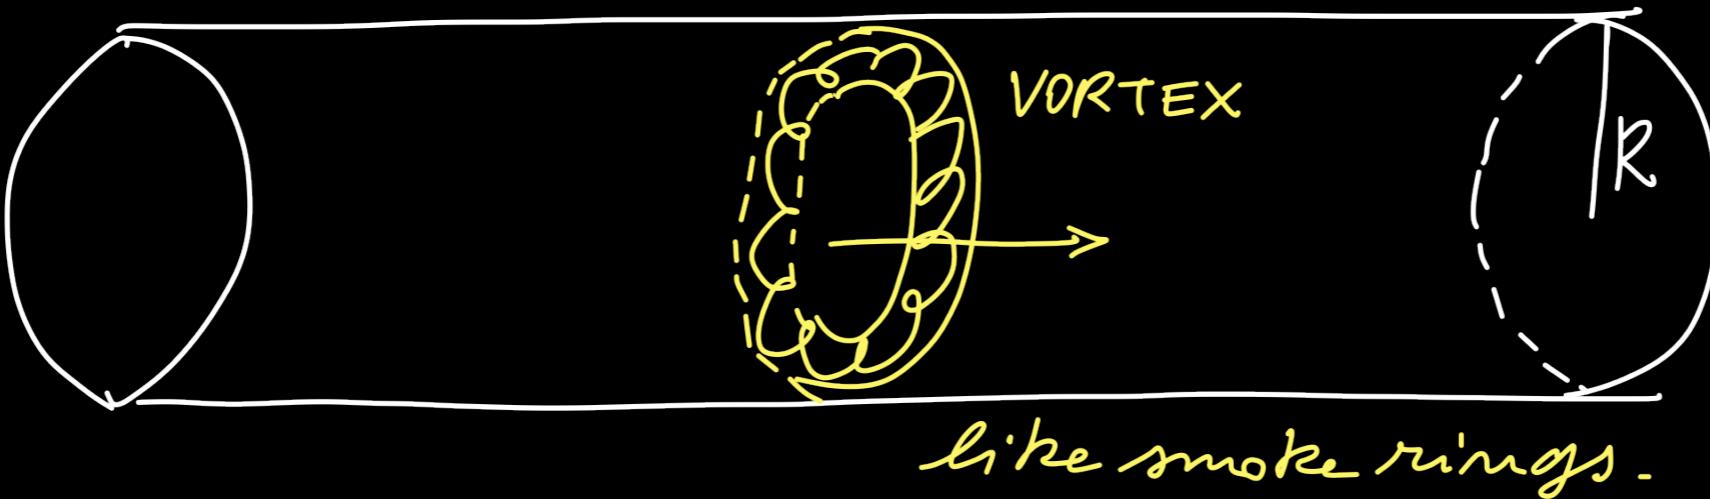

$$\epsilon(\vec{p}) = \frac{\vec{p}^2}{2m\zeta(\vec{p})}$$

$\zeta(\vec{p})$ is the Fourier component of the density correlation f.

$$\left\{ \begin{array}{l} S(\vec{r} - \vec{r}') = \frac{(n(\vec{r}) - \bar{n})(n(\vec{r}') - \bar{n})}{\bar{n}} \\ n(\vec{r}) = \frac{1}{m} \rho(\vec{r}) \quad (\# \text{density}) \end{array} \right.$$

$$S(\vec{p}) = \frac{A}{2\pi\bar{n}} \int \sigma_{nHe}(\omega) d\omega$$

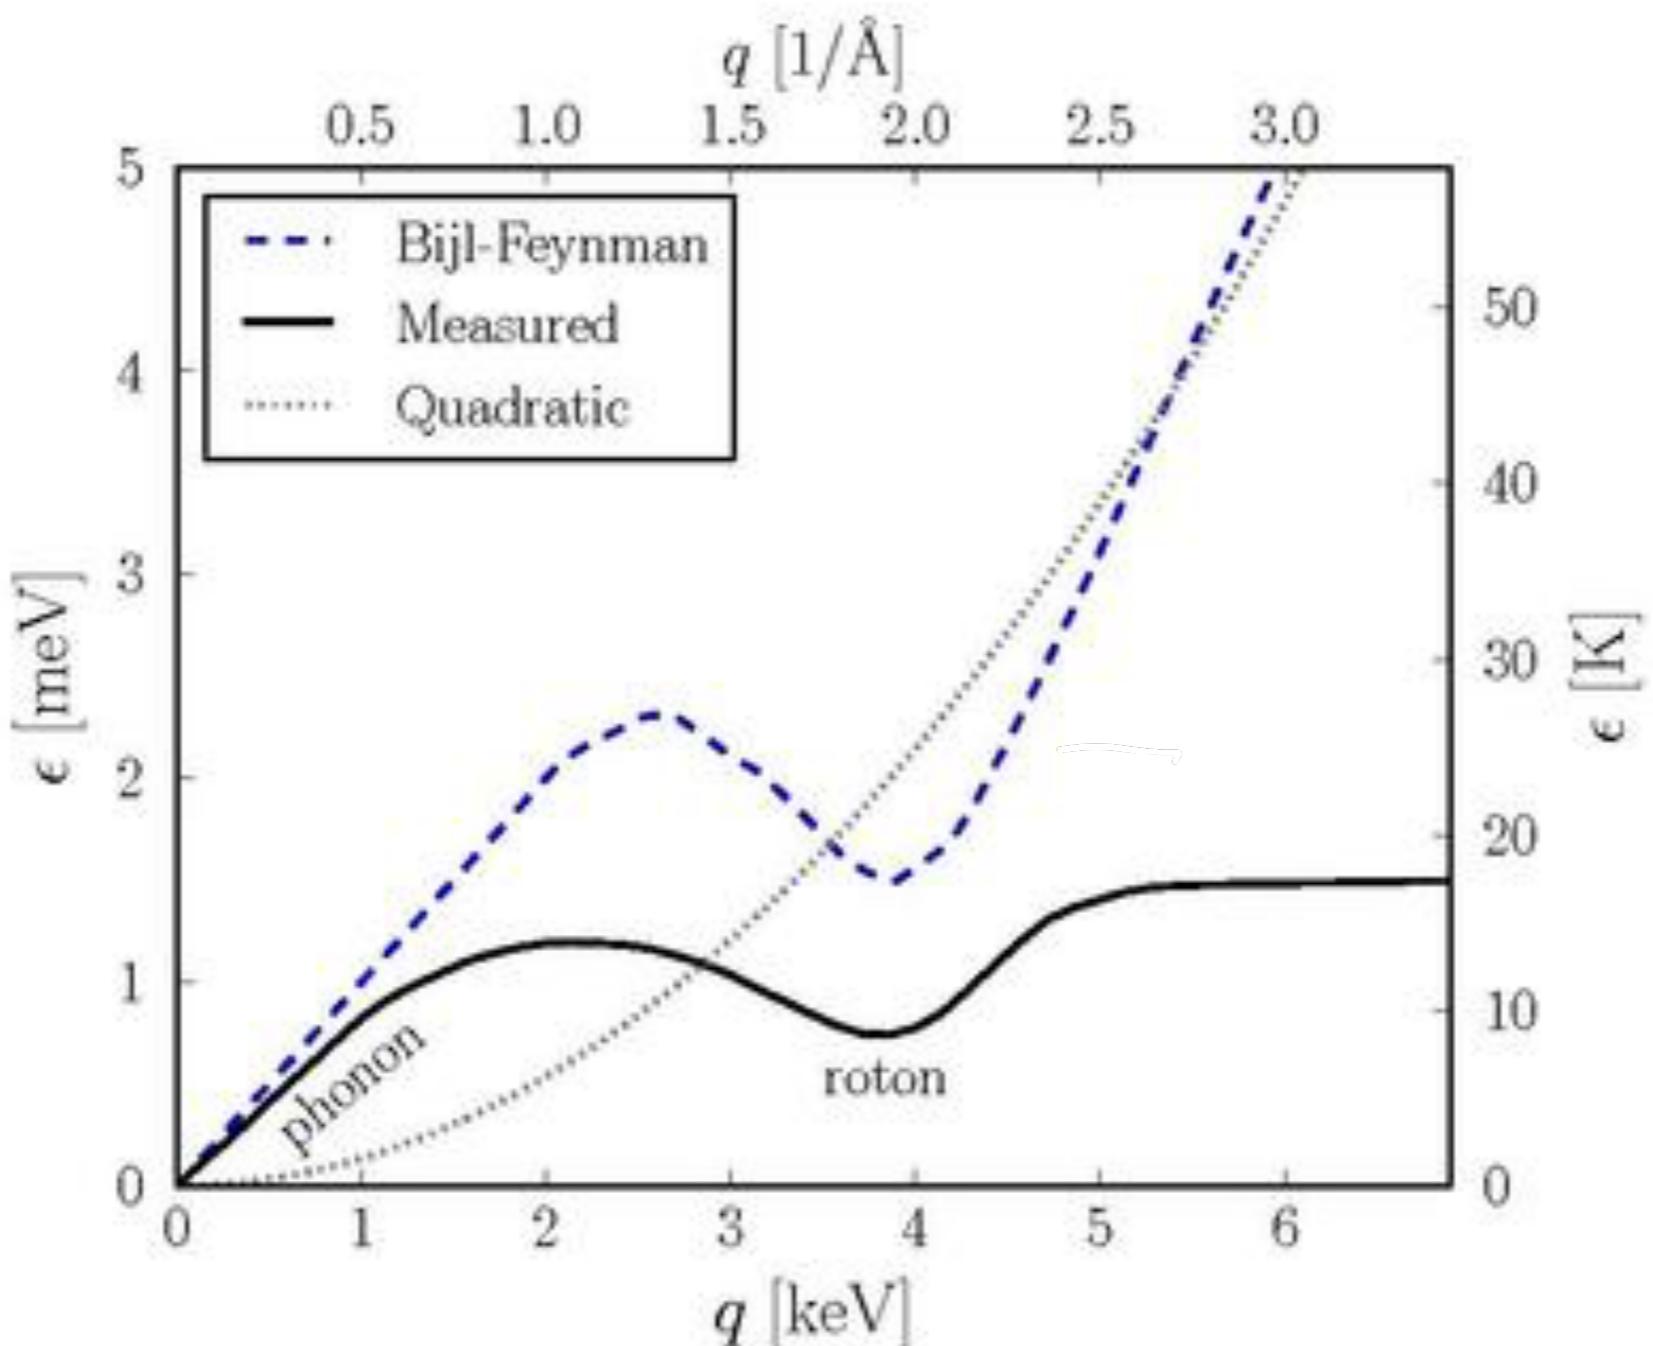

slow neutron - Helium
w/ energy transfer ω

$$\frac{E_V}{P_V} = \alpha m c_s^2 \frac{\ln \frac{R}{a}}{\frac{R}{a}}$$

$\ll \frac{e}{\phi}$ of photons & rotoms

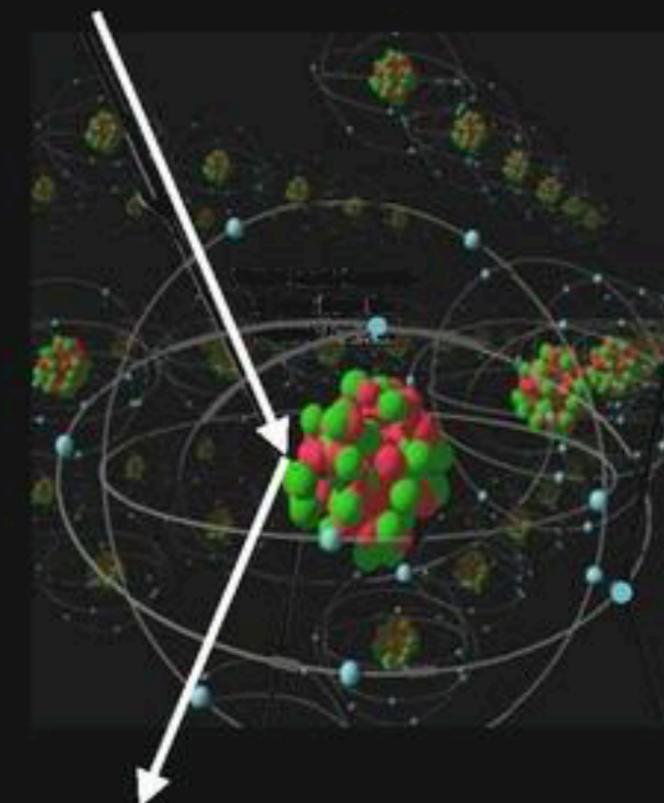

Probably the reason why the measured critical velocity is sensibly smaller than what expected from the (measured) spectrum of excitations.

Structure effects

$m_\chi > 1 \text{ MeV}$:

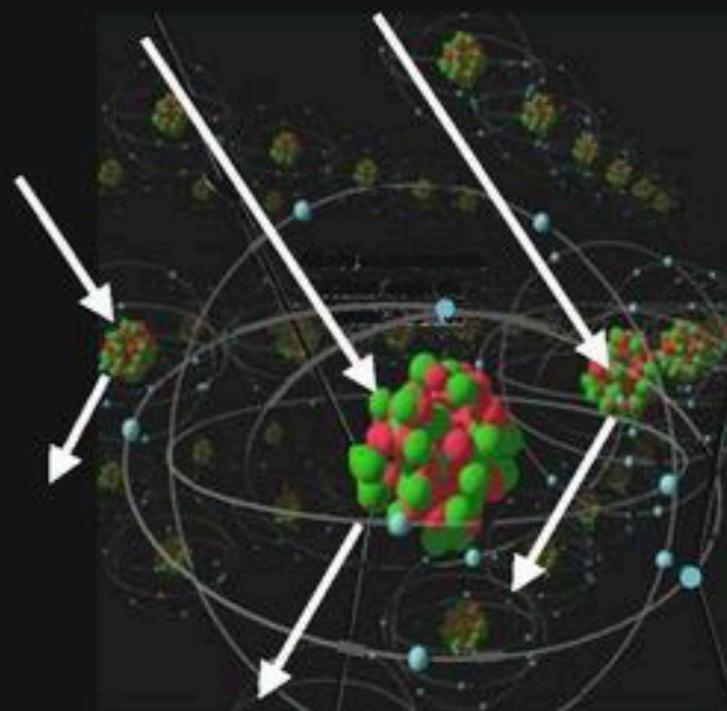

Recoil of nuclei/electrons

$m_\chi < 1 \text{ MeV}: q \approx m_\chi v_\chi < \text{keV} \sim \text{nm}^{-1}$

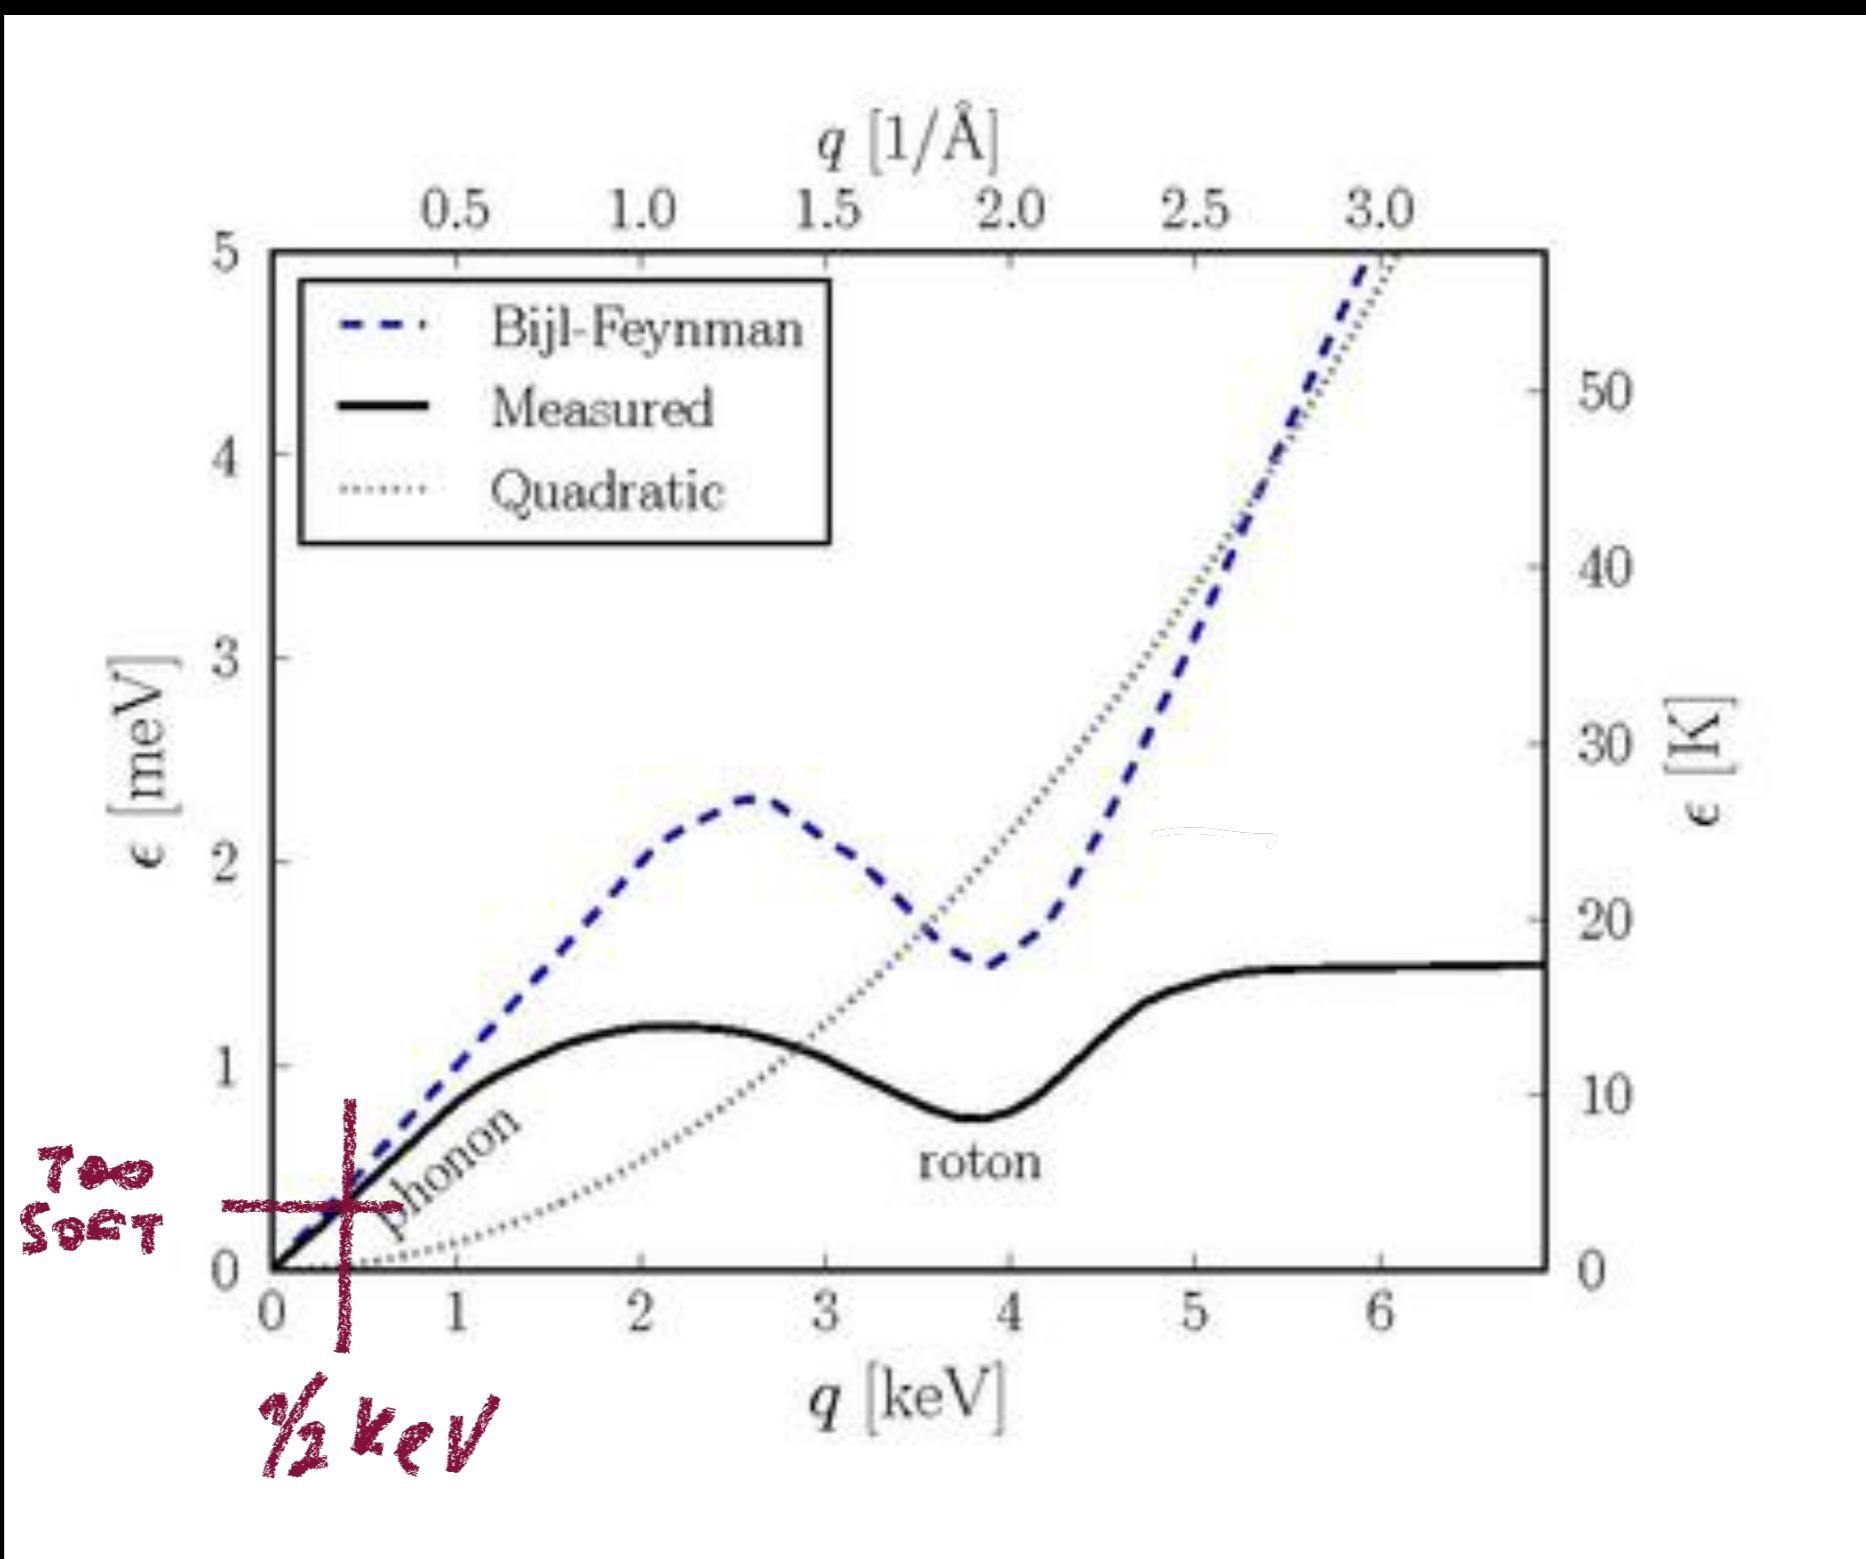

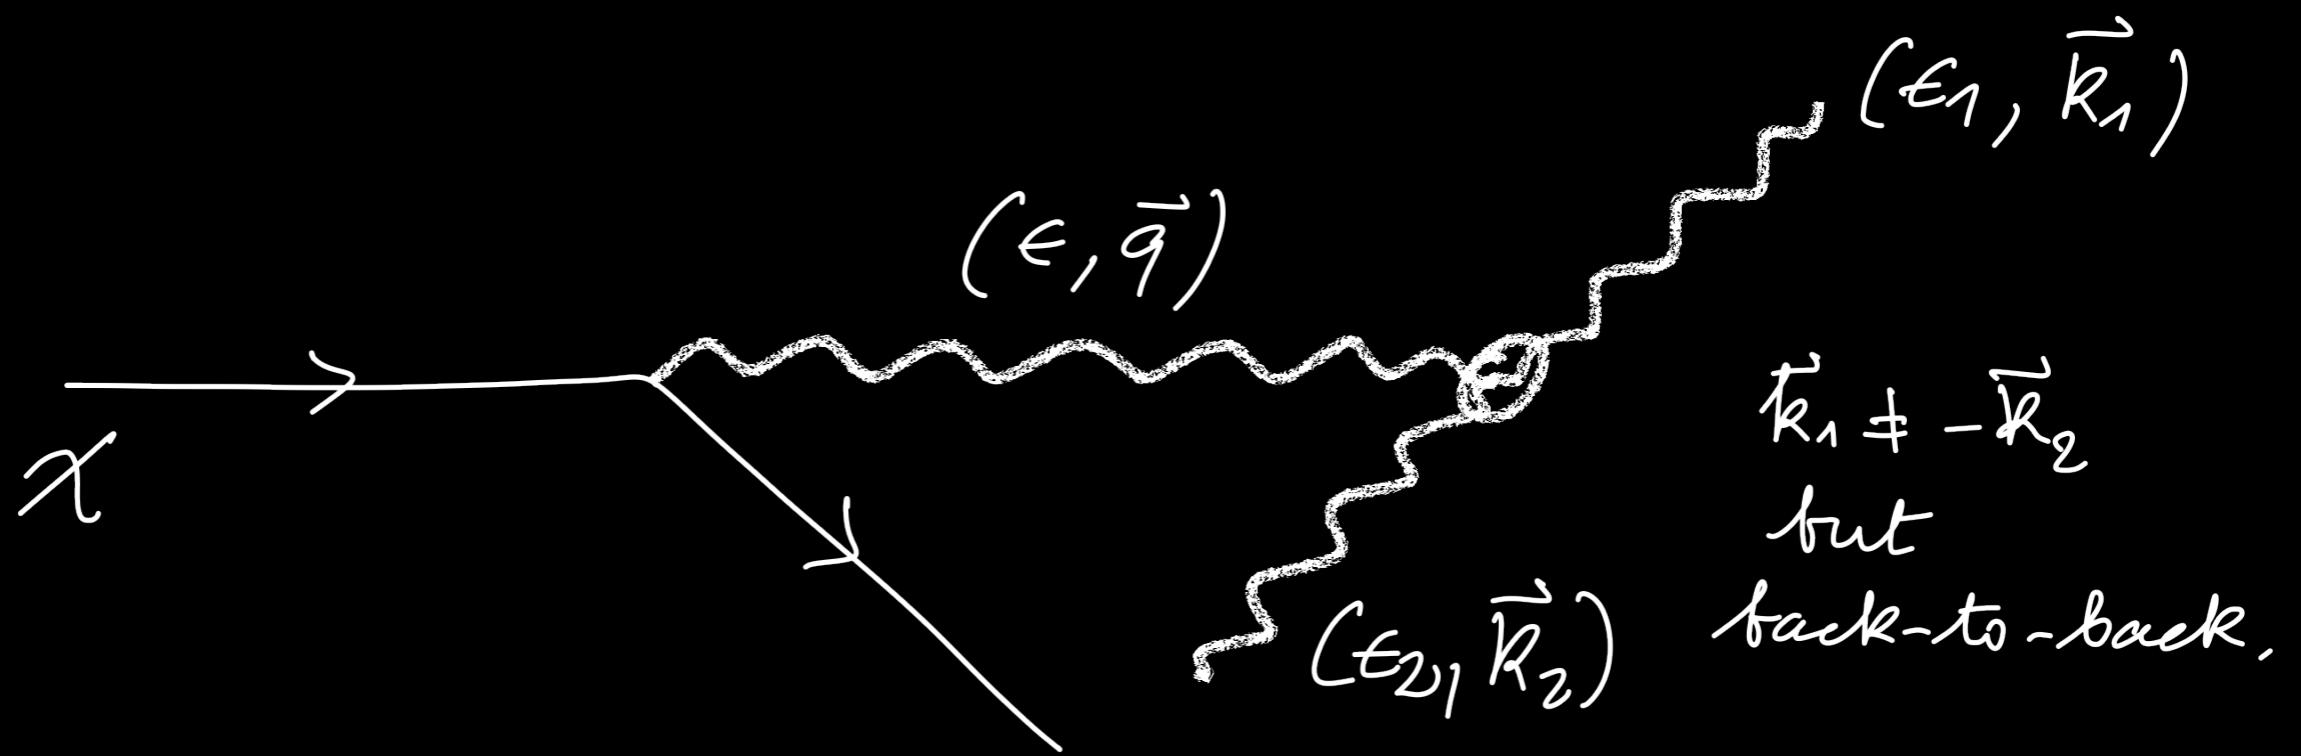

Scatter of collective excitations
(e.g. phonons)

Transition to different effective theory

Superfluid helium detector

POSSIBLE 100% DETECTION EFFICIENCY FOR PHONONS

QUASIPARTICLE W/ AT LEAST $0.62 \text{ meV} \rightarrow$ QUANTUM
 EVAPORATION OF AN He ATOM \rightarrow STICK TO A CALOR. SURFACE
 HELIUM STICKS MORE STRONGLY TO ANY SURFACE THAN IT
 DOES TO ITSELF.

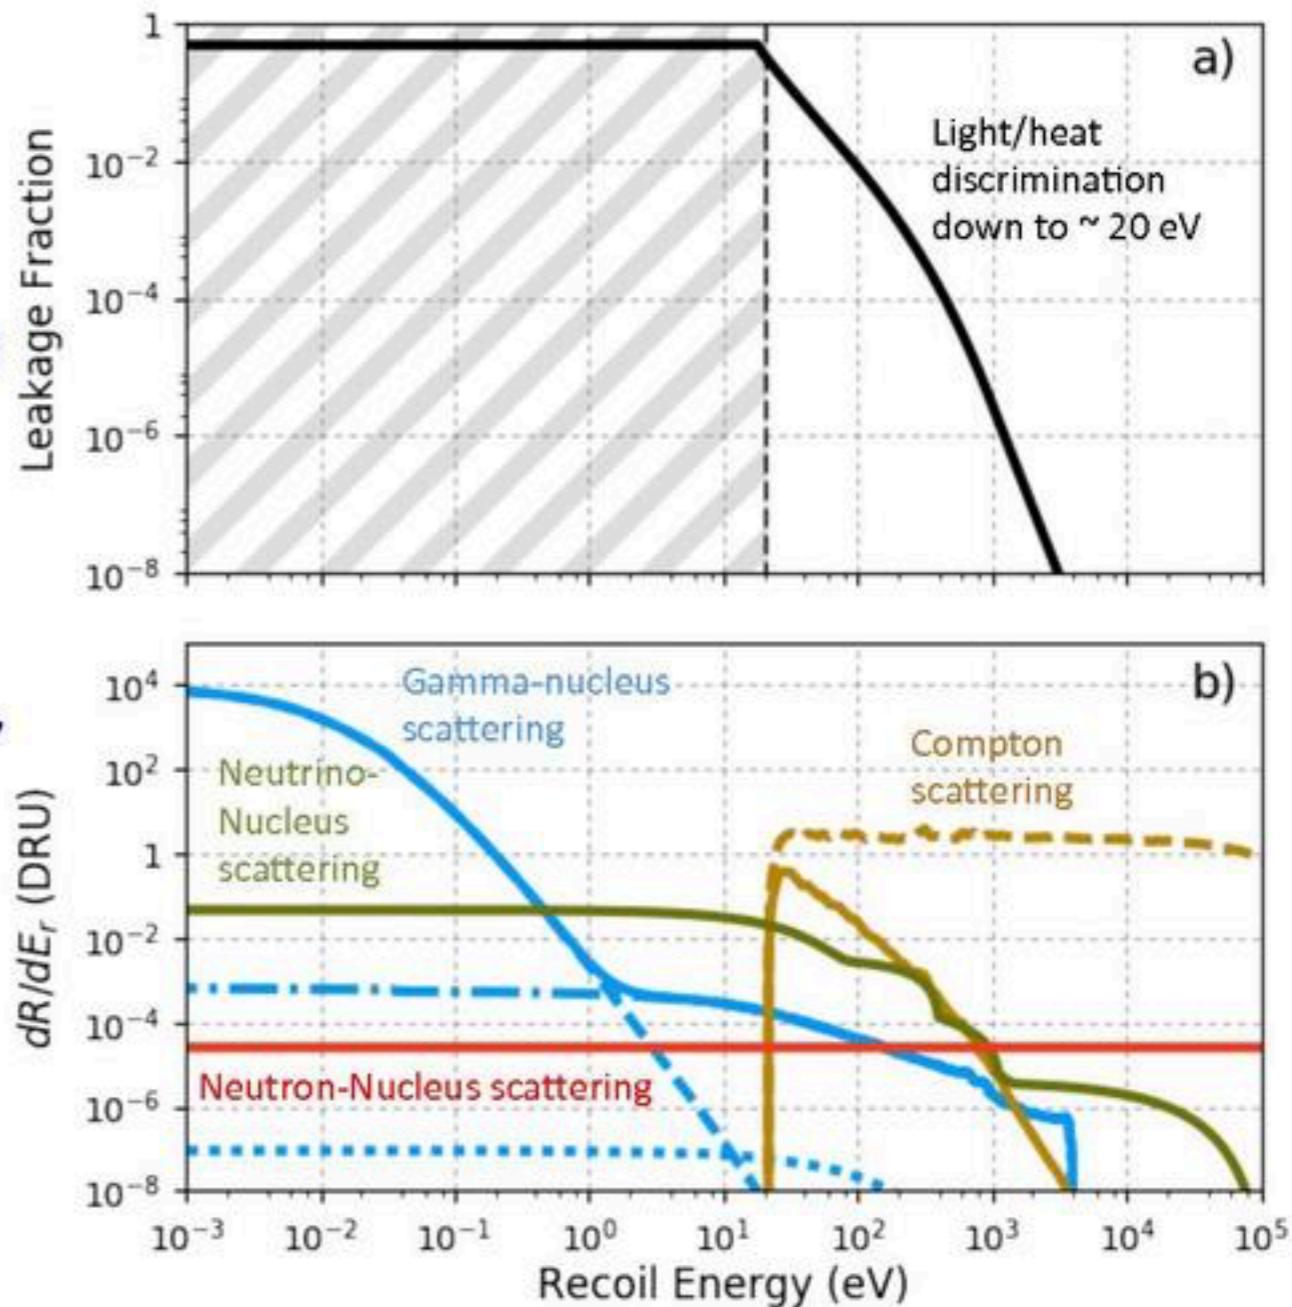

Expected Backgrounds

Backgrounds included:

- Neutrino nuclear coherent scattering
- Gamma-ray electron recoil backgrounds (similar to SuperCDMS)
- Note: Helium itself is naturally radiopure, and easily purified of contaminants
- Gamma-ray nuclear recoil backgrounds (see Robinson, PRD 95, 021301 (2017))

Arguments for low “detector” backgrounds:

- Low-mass calorimeter, easy to hold
- Target mass highly isolated from environment (superfluid: friction-free interfaces)

Projected Sensitivity – nuclear recoils
