Photon-photon dans les anneaux de stockage électron-positron 3-4 sept. 1973, Collège de France (Paris)

- Not only photon-photon but since 1997 Photon + interactions etc.

- Not in only e+e- but in pp, pA etc.

P.Kessler and the CdF group: N. Arteaga, C.Carimalo, J.Parisi
On The Storage Ring.

The following is a very sketchy proposal for the construction of a storage ring in Frascati. No literature

At this stage it appears necessary to define the project a little better: I prefer to think of it as an experiment rather than as a machine - a fact which may possibly alter our attitude to the project. As I think the project is closer to an experiment in two important respects: in cost and in applicability of the ironware. Talking of cost I propose to study the reactions

\[
\begin{align*}
(1) & \quad e^+ + e^- \rightarrow \mu^+ + \mu^- \\
(2) & \quad \pi^+ \pi^- \rightarrow 2 \pi^0 \\
(3) & \quad \pi^+ \pi^- \rightarrow 2 \pi^0
\end{align*}
\]

and I admit that I think that there is nothing else of importance, which can be studied with the same set up.

The first of the processes listed is two quantum annihilation. The process is predominantly backward-forward in the C.M. system and in these preferred directions no 'radiative corrections' are to be expected. The cross section for this process is

\[
\sigma(A) = 6.3 \times 10^{-30} \text{ cm}^2
\]

at 250 Mev and it diminishes a little less than quadratically with rising energy.

I propose to use (1A) as a monitoring process. This is a...
B. Touschek,
Rome, 9 Nov. 60.

It is proposed to construct a synchrotron
like machine capable of accelerating simultaneously
electrons and positrons in identical orbits. The suggested maximum energy is 1.5 GeV for the electrons as well as the positrons. This energy allows one to produce pairs of all the so-called 'elementary particles' so far known, with the exception of the neutrino, which only becomes accessible via a weak interaction channel.

It is assumed that experiments in which there are only two particles in the final state are most easy to interpret. There are 16 such reactions, namely:

1. $\gamma^+\chi$. This is the only reaction in which the final intermediate state is 'quasi real' and in which therefore there should be no 'radiative corrections'. This reaction should serve as a 'monitor'. The cross-section is $2.5 \times 10^{-11}$ cm$^2$.

2. $e^+e^-$. This reaction will show strong angular variations and may require 'good geometry'. It would give information on the breakdown of electrodynamics at distances corresponding to about $1/3$ the Compton wavelength of the proton.

3. $\mu^+\mu^-$. Test of electrodynamics in 'bad geometry'. May also serve as an indication of the fundamental difference between electrons and muons.

4. $p\pi^-$. Reveals the interaction between pions in odd parity states.

5. $2\pi^\pm$: charge exchange interaction for pion-pion scattering.

7. $\bar{K^0},K^0$. Charge exchange interaction between K-mesons.

8. $p,\bar{p}$. Interaction of proton and antiproton in even parity odd charge parity states.

9. $n,\bar{n}$. Same as (8) but for the charge
AdA in Frascati and Orsay: 1960-64

March 1963:
-Touschek effect is discovered and published in PRL

1963-64
-Measurements are taken of

\[ e^+ e^- \rightarrow e^+ e^- \gamma \]

-Data are compared with theoretical calculations by Altarelli and Buccella
(thesis work with Raul Gatto)

-The rate is in agreement with the theoretical calculations and Touschek’s effect: collisions are proved.

(ricavato il 16 Luglio 1964)

Summary. — The paper describes a series of experiments carried out with the purpose of observing the \( \gamma \)-rays produced in the collision between stored beams of electrons and positrons. The interaction rate has been measured and was found to be in good agreement with the hypothesis that there is a complete overlap between the two beams and that the dimensions of the beams are those calculated from the lifetime effect.
In 1971 experimental evidence for photon-photon collisions was found at ADONE and VEPP2

Evidence for two-photon production of $e^+e^-$ pairs at VEPP-2

1 – One of our colleagues Vladimir Balakin suggested that the observed events are from the $e^+e^-\rightarrow e^+e^-$ process, which was first discussed by Landau and Lifshitz in 1934.

2 – Vladimir Baier and Victor Fadin obtained the differential cross section for this process (Phys. Lett. 35B, 156, 1971).

3 - Good agreement between their calculation and experimental results validated the hypothesis on the process nature.

4 – In particular, the experimental and calculated distribution of the azimuthal discollinearity angle $\Delta\varphi$ for $|\Delta\theta| < 40$ is shown in the figure. It is seen that observed distribution well agrees with calculation, taking into account the multiple scattering and geometry of experiment.

For comparison the dashed line corresponds to independent and isotropic particle distribution.

5 – The article with the results of this experiment was published in journal Physics Letters in 1971.

(Received 10 December 1973)

The photon-photon interaction has been investigated by $e^+e^-$ collisions at about 2.7-GeV total energy. Evidence based on 34 well-identified events has been obtained for the process $e^+e^- \rightarrow \mu^+\mu^-$, hitherto unobserved. Such a process is found to occur in agreement with theoretical predictions based on the equivalent-photon approximation. Results on 74 events from the process $e^+e^- \rightarrow e^+e^-e^+e^-$ are also reported.

Electron colliding beams provide a means, at present unique, for investigating the photon-photon interaction at high energy, as pointed out by many authors.\textsuperscript{1} In the present experiment the outgoing $e^-e^-$ are detected at very small angles with respect to their incident directions, in coinci-
