# Pipelines for Gravitational Waves followup

Nicola Omodei

- **Add automatic followup with LTF - easy to do**
  - Send an e-mail to LTF to start the analysis.
- **Add a “pgwave” branch - quick and dirty - (Sara C., Gino)**
  - Produce a LAT count map from the LIGO probability map on 10 ks (TBD).
  - Detect sources with pgwave (fast)
  - Some plots will be added to the results
  - Followup analysis with LTF (see above)
- **Calculate probability maps:**
  - from TS to something meaningful!

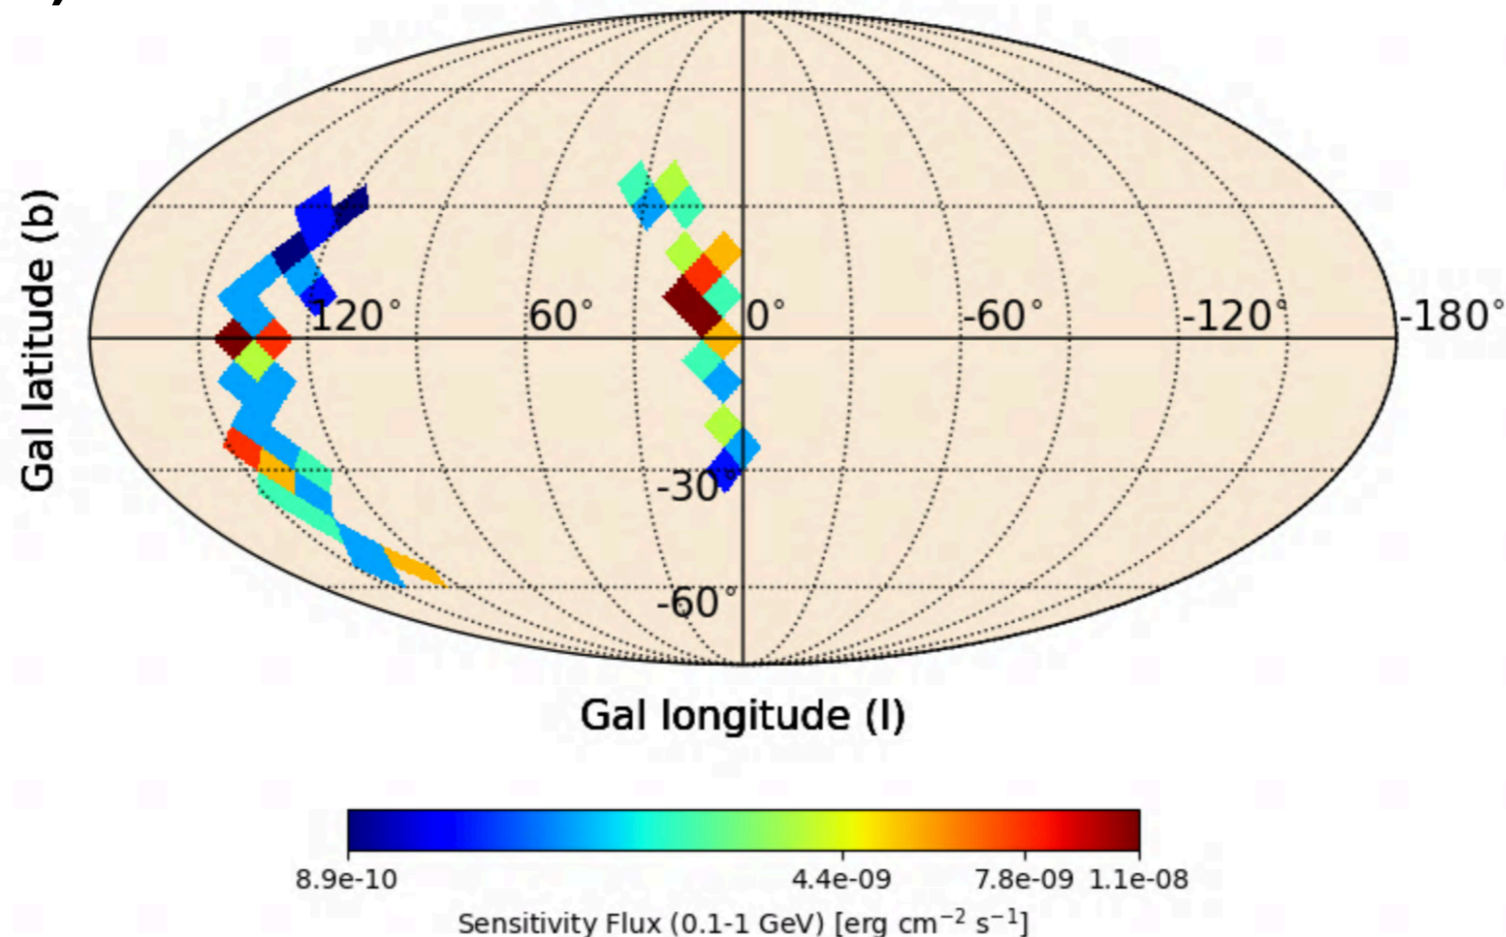

- **Work started by Lorenzo, Rupal and Milos**
  - From the TS map, we could create probability maps depending on the number of pixel we search (effect trial factors)
    - **Calibrating the p-value distribution**
  - “The more you look, the less you find” effect!
    - **Using the LIGO probability map as prior, we can set up a searching strategy to decrease the number of trials, limiting the region only to hot spots.**

# Estimating the sensitivity

- **Fix the threshold probability (5 sigma): estimate the flux such that we detect a source 50% of the time, for a given  $Ts_{\text{eff}}=30$  (see Lorenzo's talk)**
- **This is the flux upper limit (as opposed to upper bound) which is an estimation of the sensitivity to transient sources (as opposed to the estimation of the flux of a source compatible with the observation).**

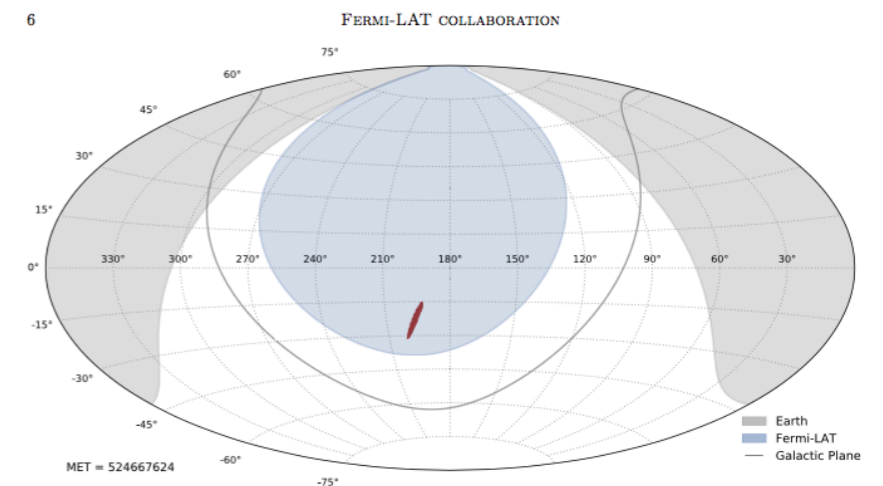

- **The Pipeline at SLAC is automatically triggered by e-mail**
- **Hard at SLAC machines to use mysql and web servers:**
  - Move results file at Stanford, store them in a database
  - Using the same infrastructure than <http://fermigrb.stanford.edu> (supeople, Ieland)

- **Localization might not be an issue for some joint LIGO/Virgo events ~ 30% of the cases**
  - No need to scan large region of the sky: followup strategy similar to standard GRB
    - **Lat Transient Factory and BATool triggered on GW GCN.**
  - Still for the majority of cases these infrastructures will be needed

- **Localization might not be an issue for some joint LIGO/Virgo events ~ 30% of the cases**
  - No need to scan large region of the sky: followup strategy similar to standard GRB
    - **Lat Transient Factory and BATool triggered on GW GCN.**
  - Still for the majority of cases these infrastructures will be needed
- **Long time monitoring**
  - Given the surprisingly long X-ray afterglow of GW171017, and the fact that we don't really know much about the source, we should keep monitoring all the sources detected in GW

- **Results exported to ASDC**

- Using ASDC facility for:

- Cross correlation with catalogs (2Mass Redshift Survey - 2MRS: <http://tdc-www.harvard.edu/2mrs/> or others)

- Note: the LIGO maps contain information also on the distance (3D), therefore small group of local galaxies can be selected knowing the location and the distance (independently from the LAT results).

# Playing with Bayesian priors

**Galaxies in the GLADE catalog (<http://aquarius.elte.hu/glade/>) within the 90% credible volume (simulated source). From Del Pozzo et al., 2018 (<https://arxiv.org/abs/1801.08009>)**

**Similar techniques (2MRS catalog?) have been crucial in determining which galaxies to point for 170817.**
