

Why do S1 light yield  
increase with time?

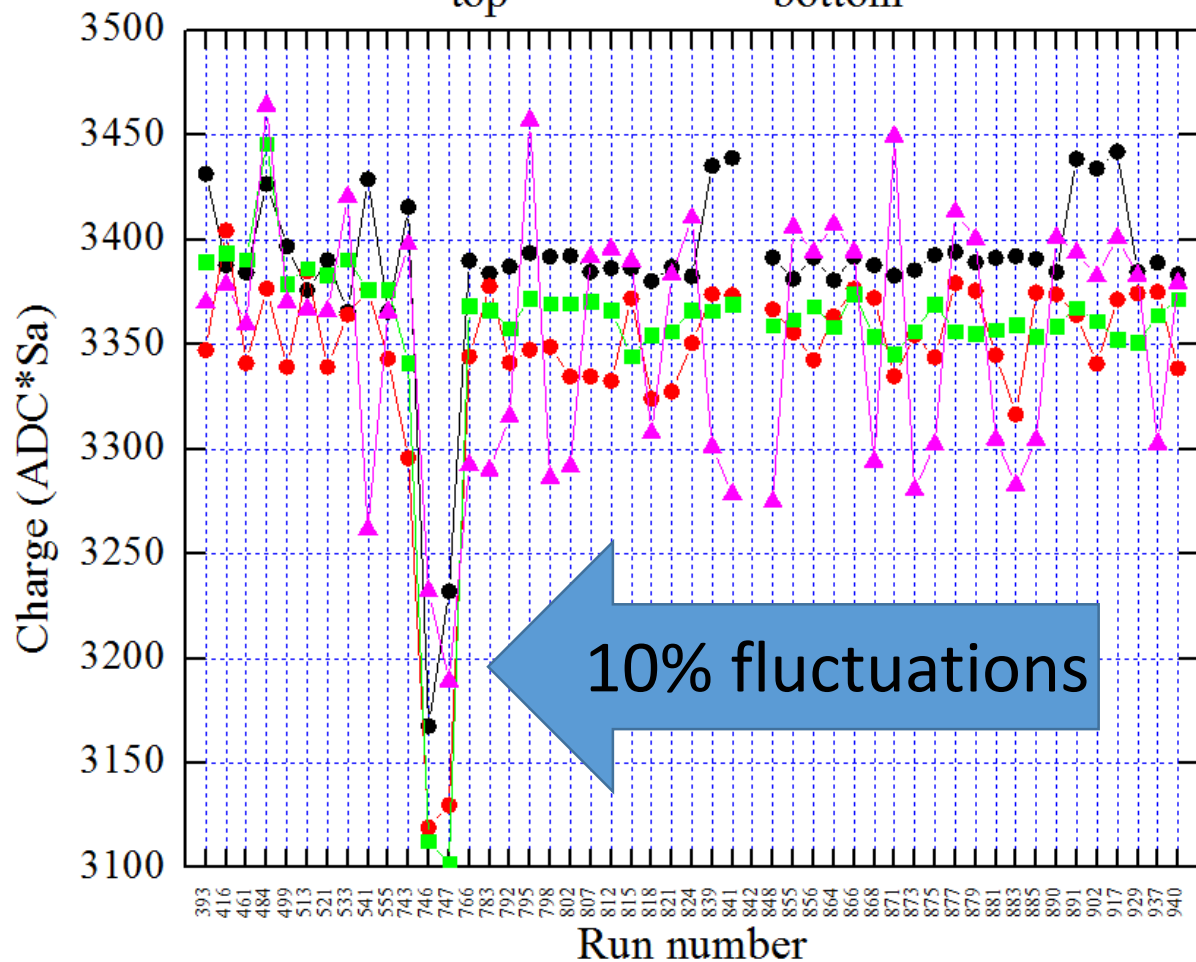

ReD call 1 April 2019  
Oleynikov Vladislav

Am241 Field off S1 mean vs time

SERs are  $\sim 1\%$  stable, except 10% fluctuations

$V_{\text{top}} = 34; V_{\text{bottom}} = 68$

Camp-VII

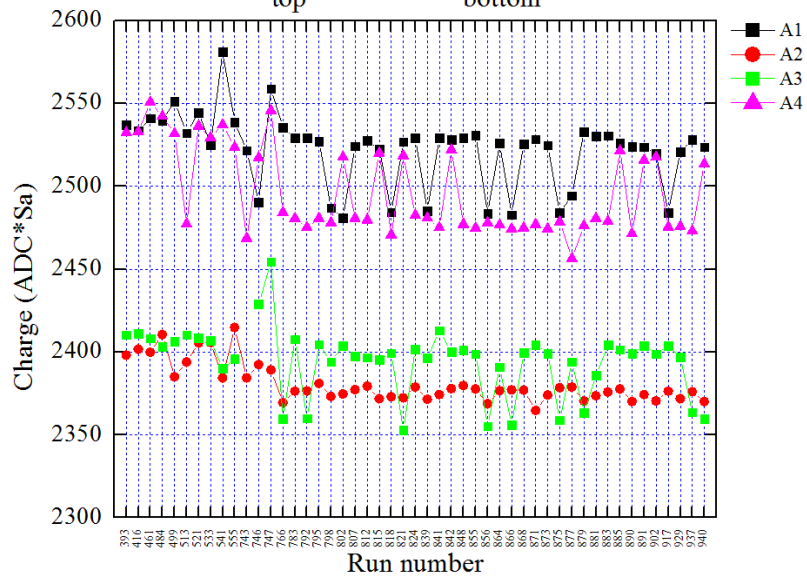

$V_{\text{top}} = 34; V_{\text{bottom}} = 68$

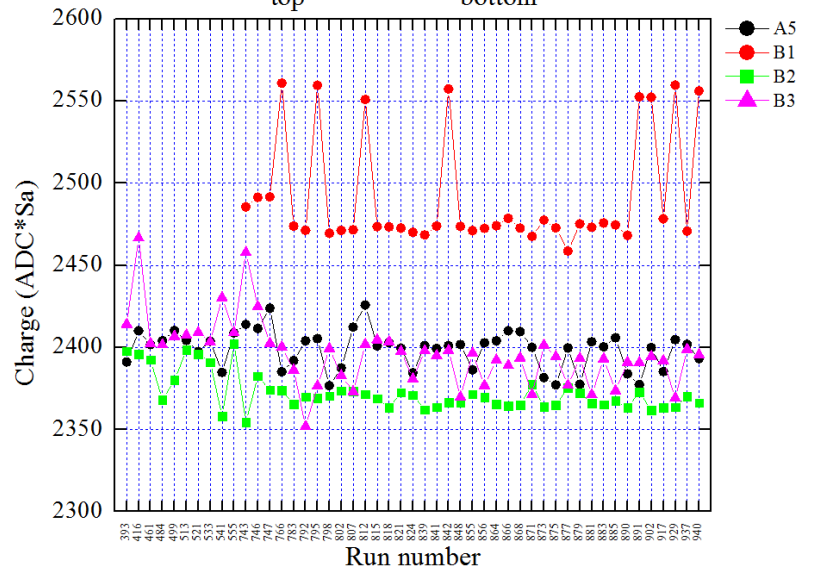

Camp-VII-2, Camp-VII-3

$V_{\text{top}} = 34; V_{\text{bottom}} = 68$

$V_{\text{top}} = 34; V_{\text{bottom}} = 68$

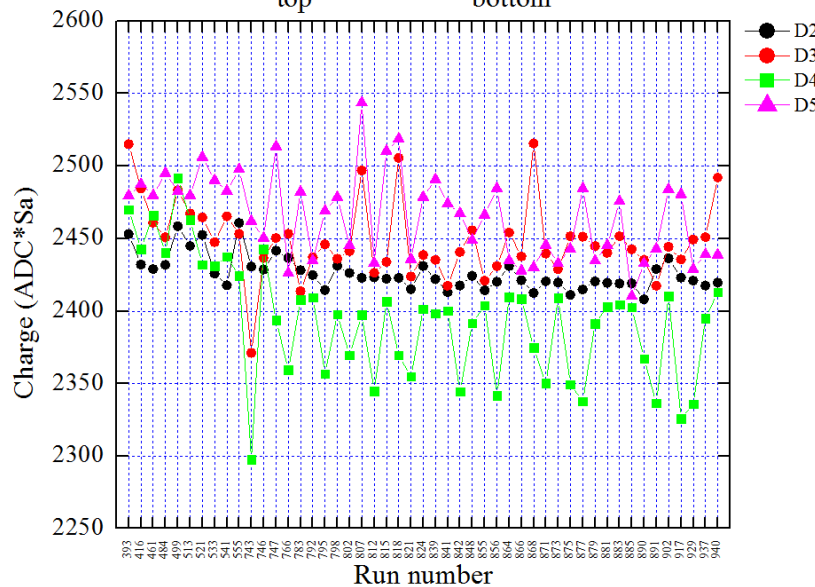

$V_{\text{top}} = 34; V_{\text{bottom}} = 68$

$$\text{Fit: } y = A * ( 1 - \exp[ -k * (x - xc) ] )$$

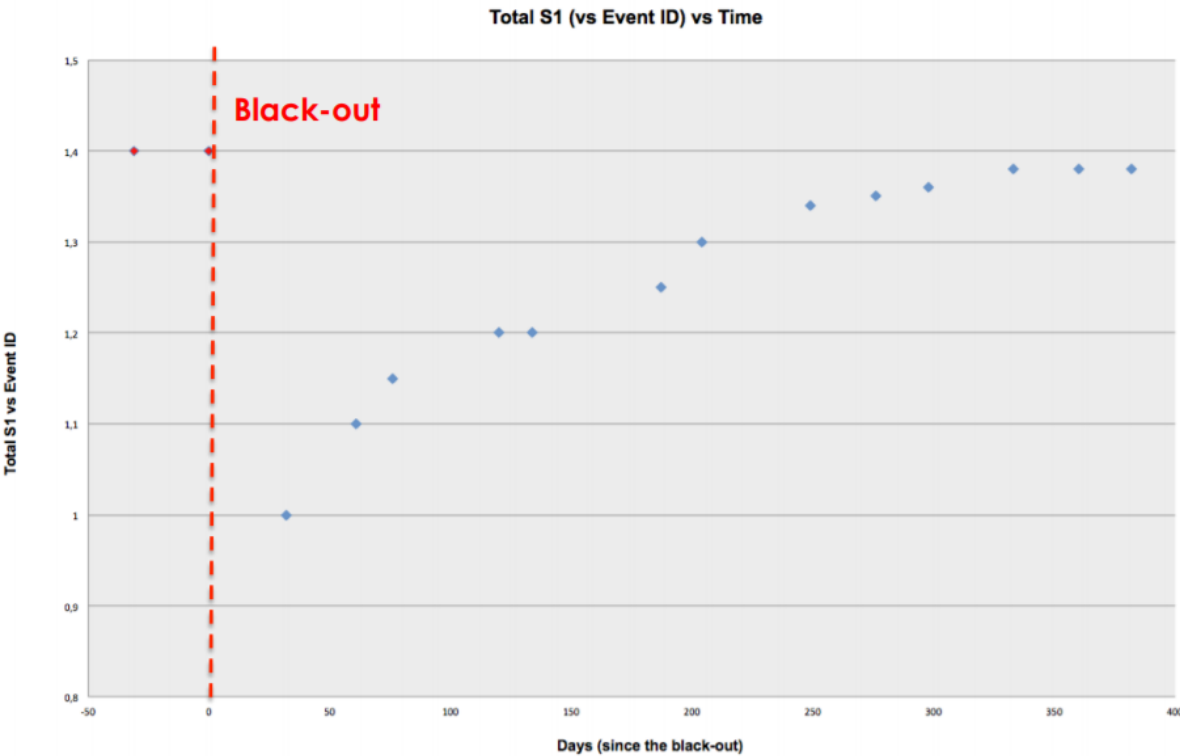

Such dependency with time looks like to some physical process.

630 PE -> 710 PE (12.7%) in 60 days

S1 increases with time in Ds-50 too.

## DS-50 UAr – Data Taking

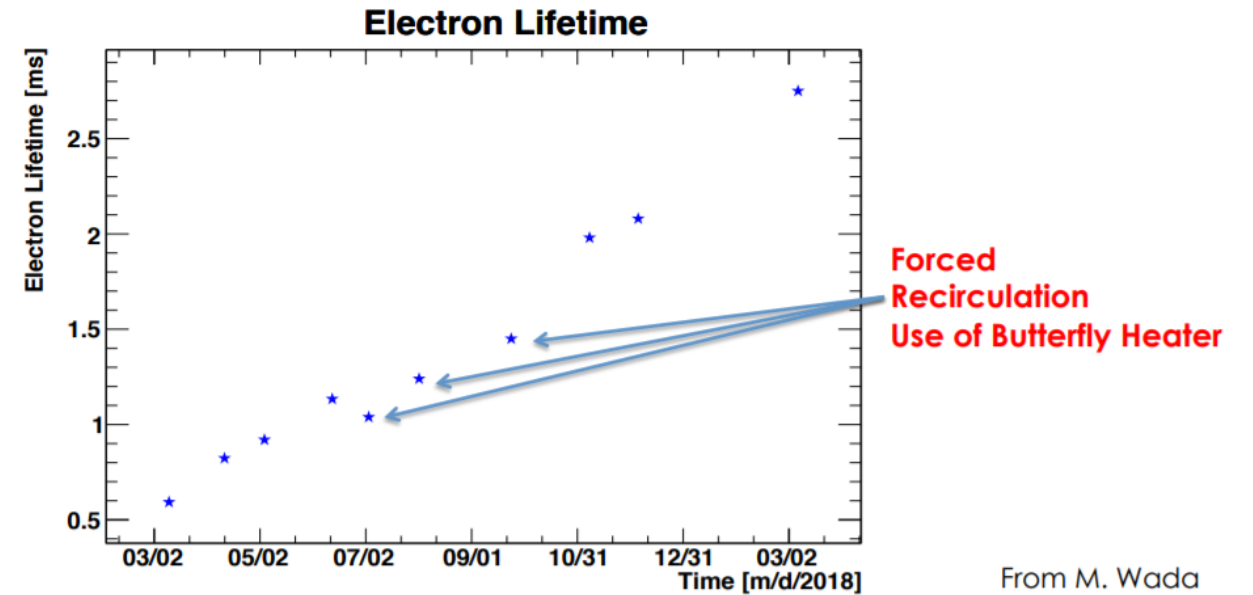

### Data Taking – S1 vs Event Id Time Evolution

## DS-50 UAr – Data Taking

### Time Evolution of the Electron Lifetime

- ▶ Two different behaviors
- ▶ Slow improvement over 1 year operations
- ▶ Far from >10 ms extrapolated value

## 2.2 Scintillation light quenching

Residual O<sub>2</sub> contamination leads also to a substantial reduction of the scintillation light intensity. This may be attributed to a quenching process in two-body collision of O<sub>2</sub> impurities with Ar<sub>2</sub><sup>\*</sup> excimer states:

## 2.3 Scintillation light absorption

Scintillation photons have energy lower than the atomic Ar first excited state, therefore pure LAr is transparent to its own scintillation radiation.<sup>6</sup> However, absorption mechanisms should be taken into consideration in presence of contaminations of photo-sensitive molecules potentially diluted in LAr. In this case emitted photons may be absorbed regardless from the type of precursors, singlet or triplet excimer states, they originate from. This implies that the *total* light yield available for detection can be reduced, depending on the concentration of the photo-sensitive impurity, but no modification of the time constants of the scintillation signal is expected.

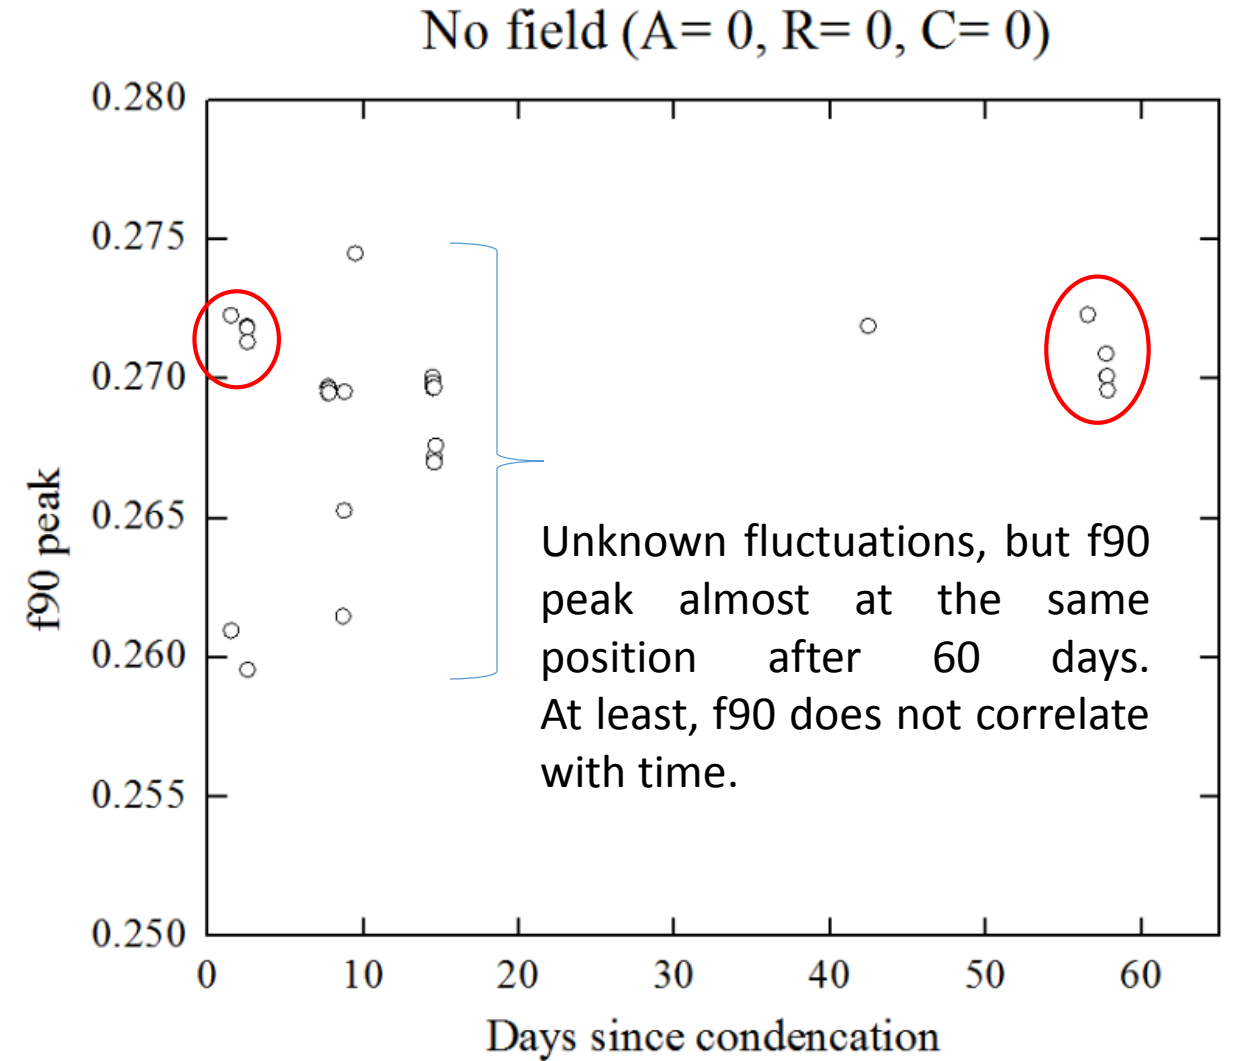

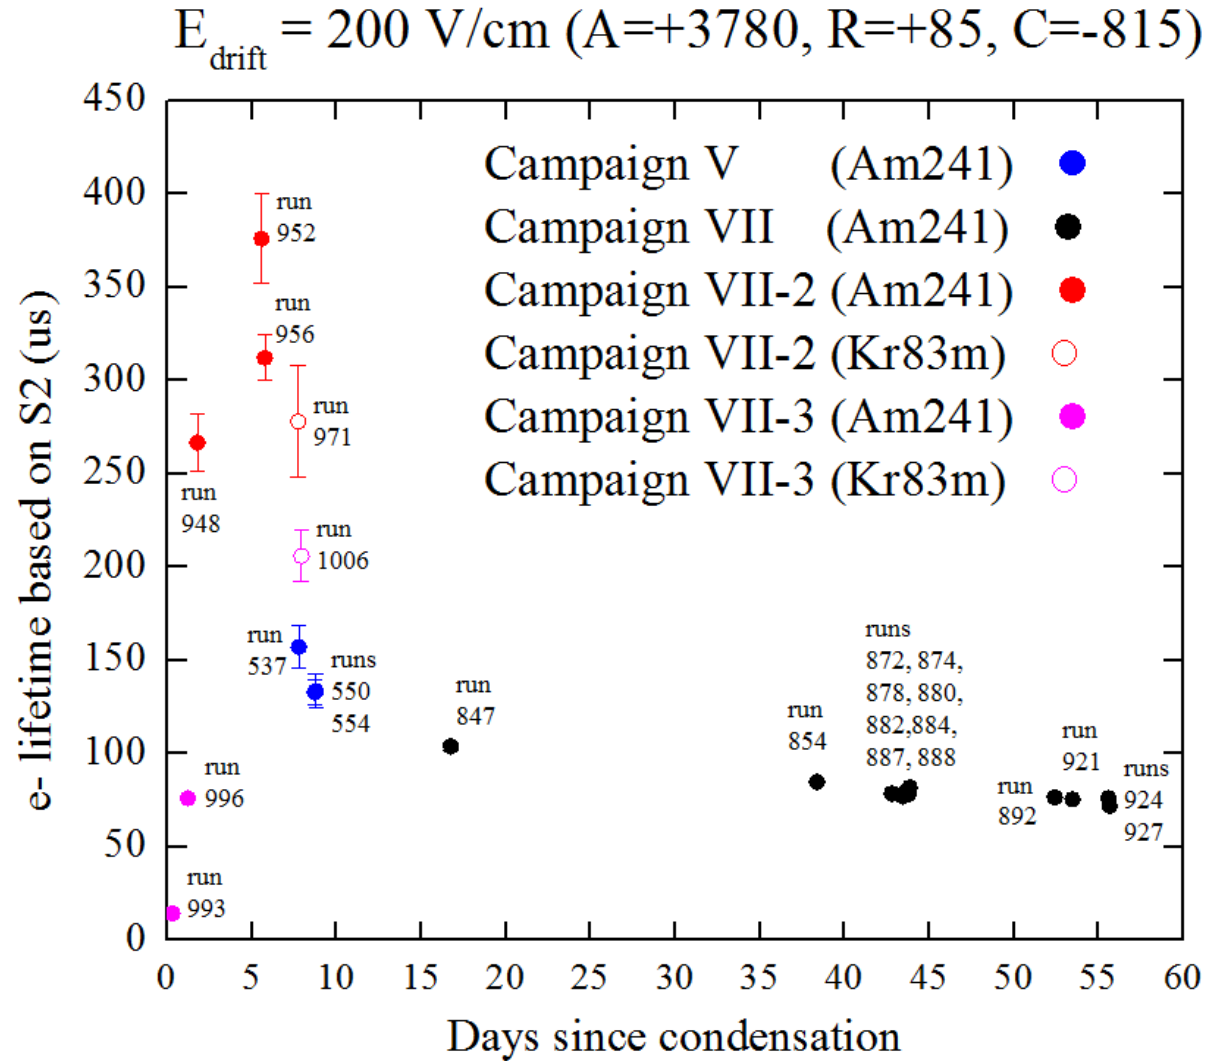

First hypothesis: S1 increases with time because [O2] and [N2] decreases.

“An intermediate component is also found to be present (as sometimes reported in literature), whose origin could presumably be ascribed to PMT instrumental effects”.

First hypothesis: S1 increases with time because [O2] and [N2] decreases.

# First hypothesis: S1 increases with time because [O2] and [N2] decreases.

$E_{\text{drift}} \sim 200\text{V/cm}$ : (A= +3780, R= +85, C= -815)

$V_d \sim 50 \text{ mm} / 62 \text{ us} = 0.81 \text{ mm/us}$

$E_d \sim 0.2 \text{ kV/cm}$

$K [\text{ppm} * \text{mm}]^{-1} = 0.95/E^{0.8} \sim 3.44$  (at 87 K)

(from Barabash, Bolozdynya. ISBN 5-283-04049-6)

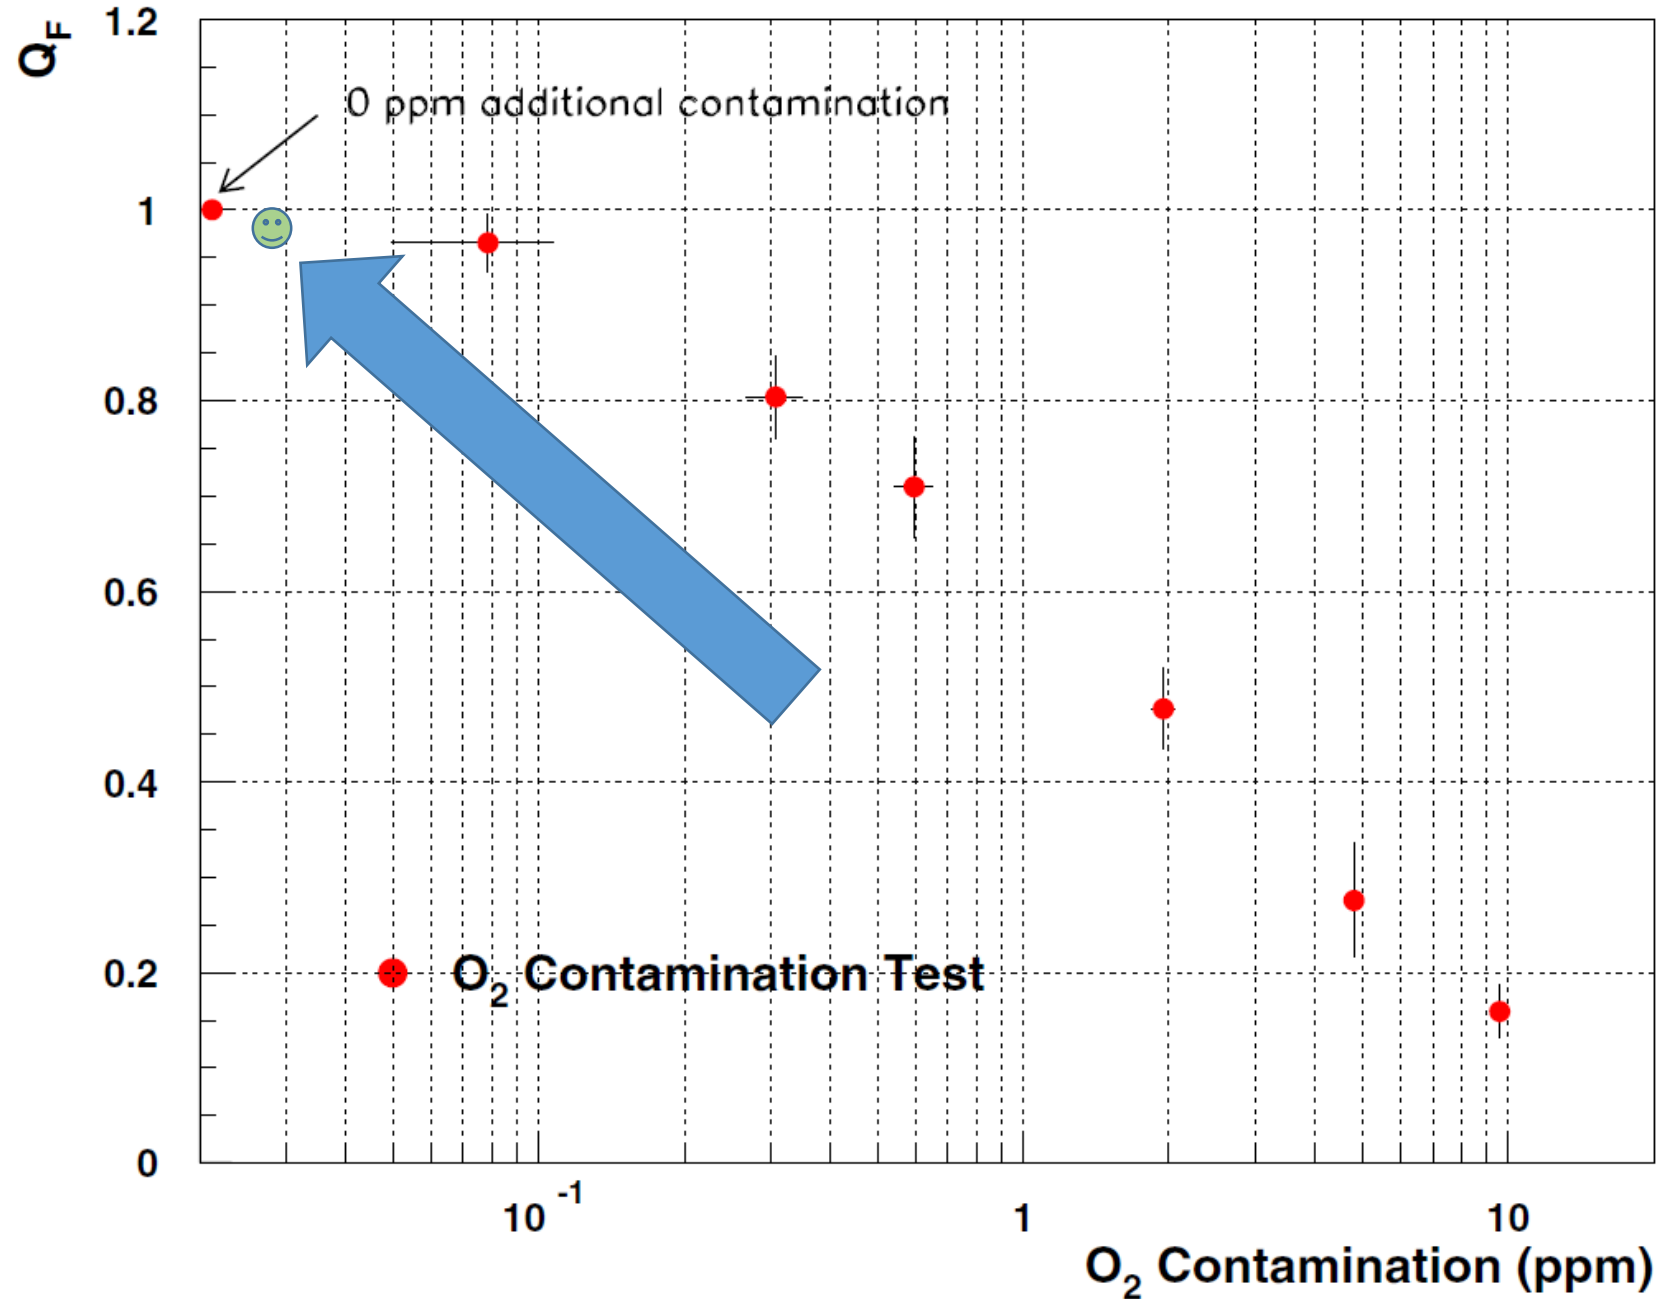

$C [\text{ppm}] = (V_d * \tau_e * K)^{-1}$

$C (15 \text{ us}) \sim 24 \text{ ppb}$

$C (400 \text{ us}) \sim 0.9 \text{ ppb}$

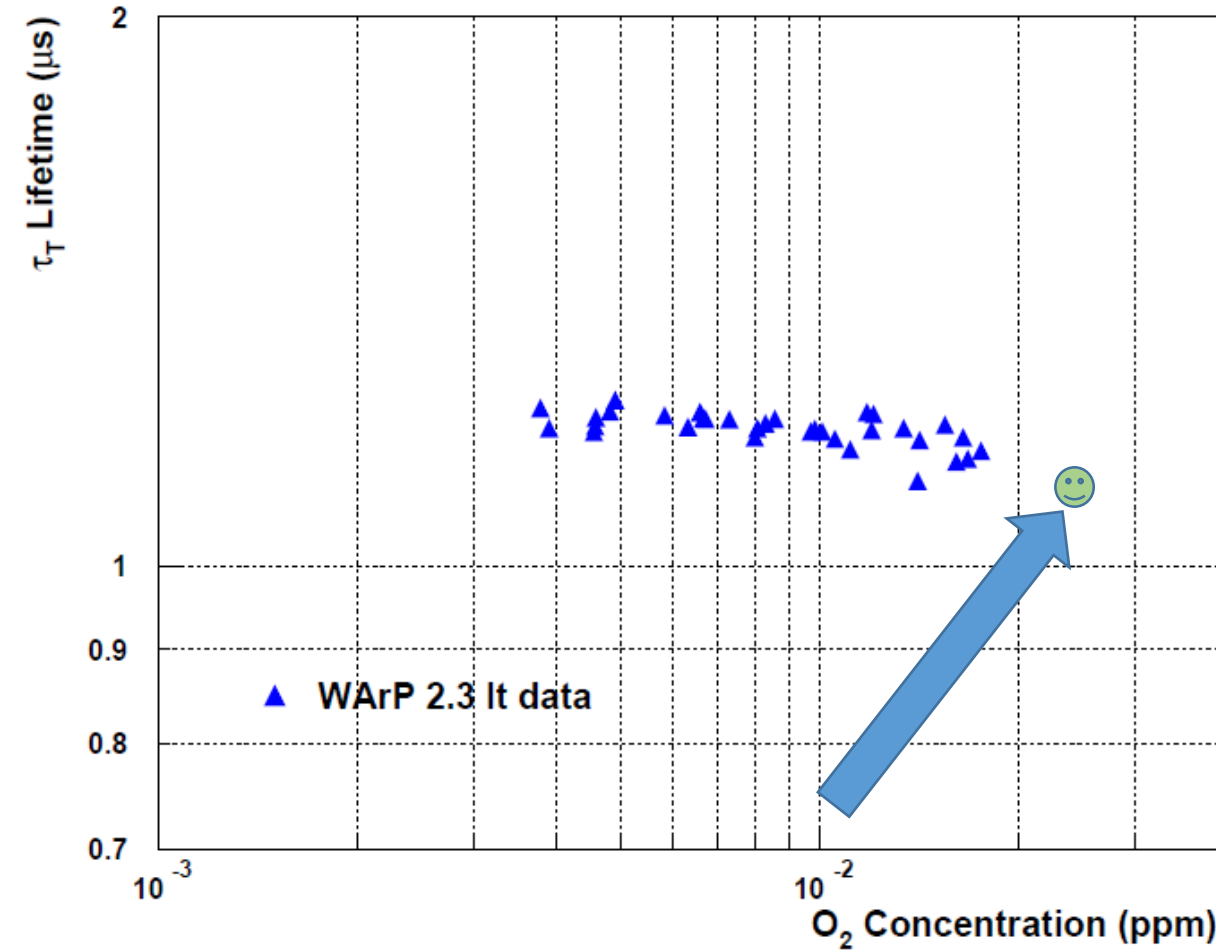

S1 correlate, anticorrelate and doesn't correlate with e- lifetime. So, I would conclude, that there are no dependency between S1 and e- lifetime in our experiment.

First hypothesis: S1 increases with time because [O2] and [N2] decreases.

15 us ~ 24 ppb [O<sub>2</sub>]  
S1 \* 0.95

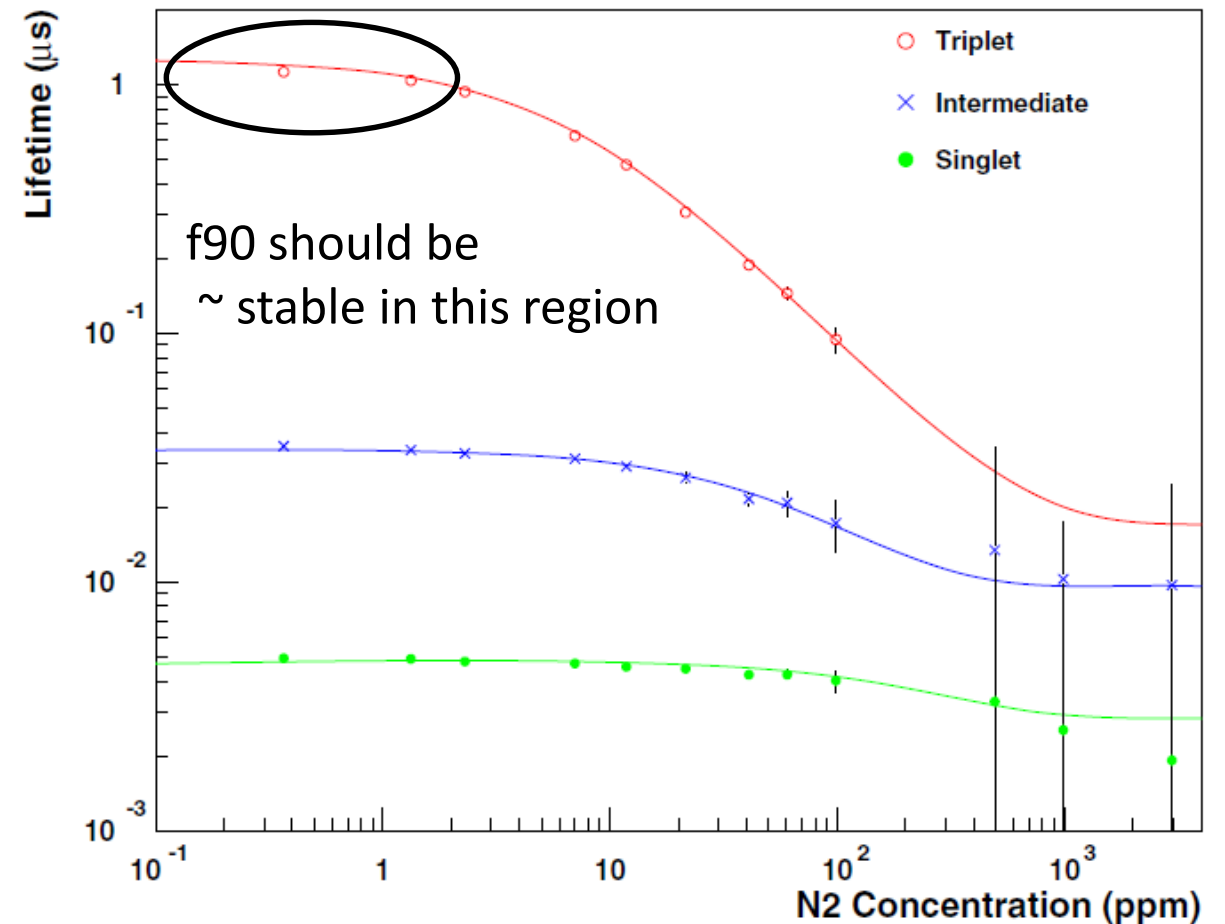

First hypothesis: S1 increases with time because [O2] and [N2] decreases.

15  $\mu\text{s}$   $\sim$  24 ppb [O2]

very small changes of tau\_triplet -> f90 is stable

First hypothesis: S1 increases with time because [O2] and [N2] decreases.

S1 can increase with time if [N2] decreases with time.

# Second hypothesis: S1 increases with time because of TPB dehydration.

[10.1016/0168-583X\(96\)00318-7](http://dx.doi.org/10.1016/0168-583X(96)00318-7)

A number of the TPH and TPB samples were repeatedly retested over a six month period. During this time they were sealed in petri dishes and kept in a dark cupboard (to avoid the large degradation which would result from a continuous exposure to sunlight). Fig. 8a, b shows the ageing effects at the end of this period due to oxidation and hydration for the two fluors, random errors are shown only. The deterioration occurred steadily and is worse at the optimum thickness of the WLS and corresponds to a decrease in efficiency of 10–15%. It should be noted that,

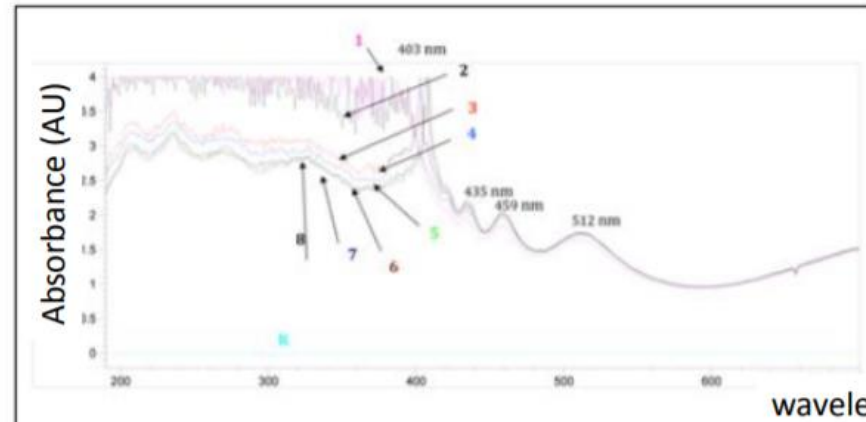

Fig. 8. Deterioration in efficiency of TPH and TPB after a six month period (175 nm incident light).

## WArP and CERN CCS Study

TPB hygroscopicity + mechanical stability to thermal cycles

From:  
[“The WArP Programme”](#)  
 R. Acciarri et al.

| TPB run | Description             |
|---------|-------------------------|
| 1       | pos 1 (quartz TPB)      |
| 2       | pos 2 (TPB quartz)      |
| 3       | pos 2 after 30 minutes  |
| 4       | pos 2 after 50 minutes  |
| 5       | pos 2 after 100 minutes |
| 6       | pos 2 after 145 minutes |
| 7       | pos 2 after 225 minutes |
| 8       | pos 2 after 285 minutes |
| 9       | reference quartz cell   |

Up to ~30% degradation in light absorbance

Figure 15: Absorbance of TPB as a function of wavelength. The efficiency decreases with time is due to water absorption. Vacuum pumping (or exposure to flow of dry atmosphere) ensures full recovery.

### Conclusion:

- Efficiency decreases with water absorption
- Vacuum pumping ensures full recovery

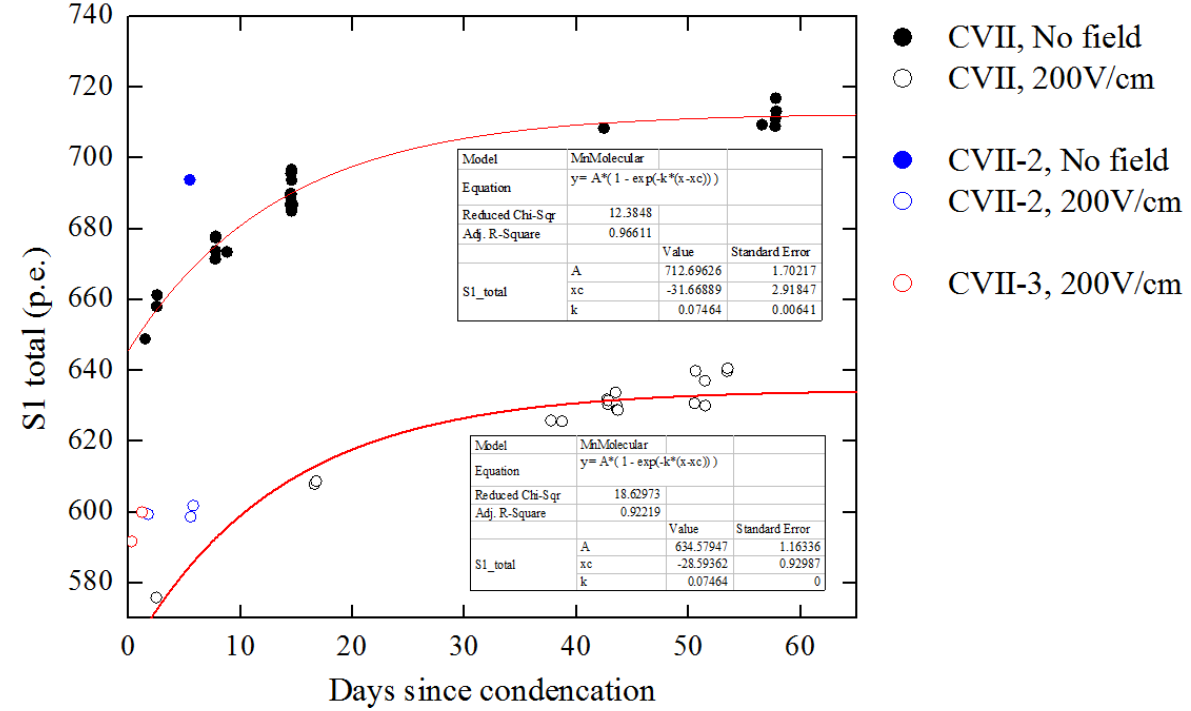

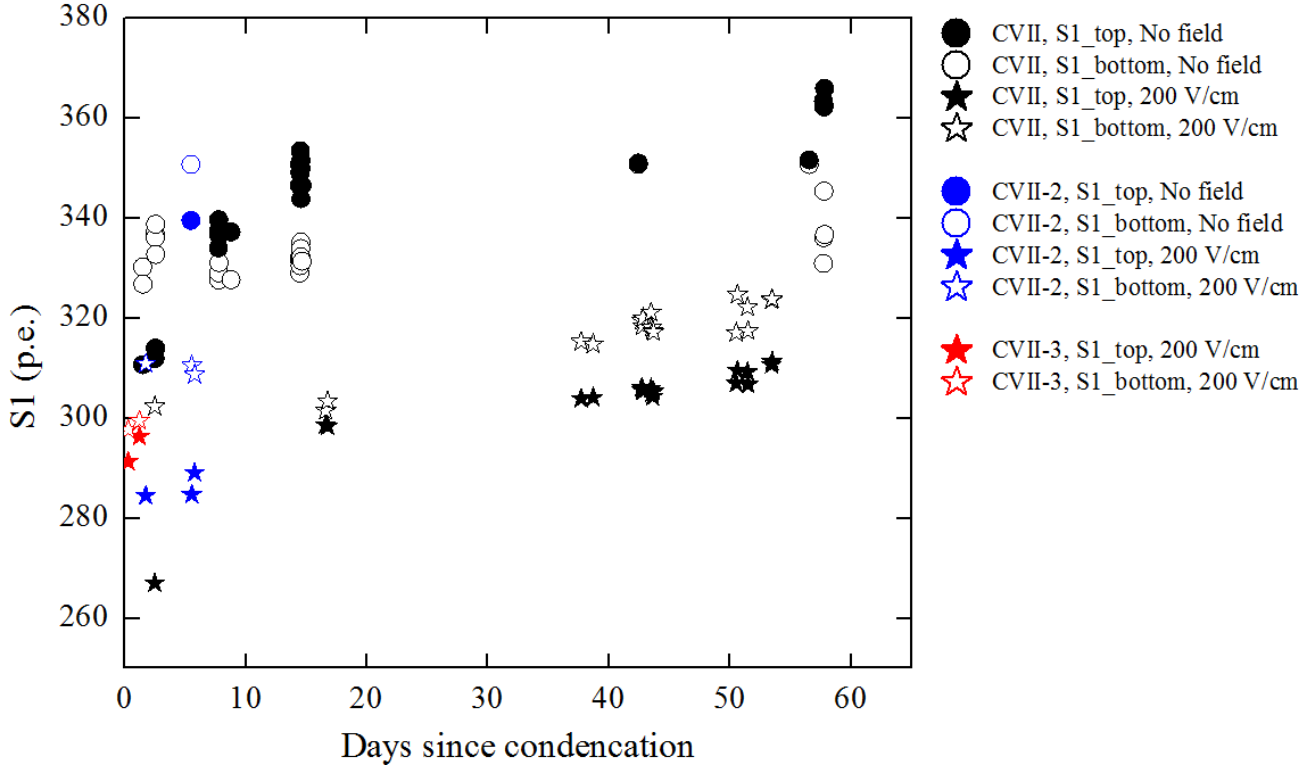

**Good news: Reversible effect !**

No field: (A= 0, R= 0, C= 0)  
 E\_drift ~200V/cm: (A= +3780, R= +85, C= -815)

No field: (A= 0, R= 0, C= 0)  
 E\_drift ~200V/cm: (A= +3780, R= +85, C= -815)

CVII:

Why S1\_top increase, but S1\_bottom ~ stable (field ON and OFF)?

Hypothesis: after LAr condensation TPB in the liquid quickly returned most part of the water, so S1\_bottom was almost stable with time, when we started to measure.

TPB in the gas returned water too, but slowly.

## Conclusions:

- Changes in [O<sub>2</sub>] can't explain ~13% increasing of S1 light yield with time. Even in the worst case O<sub>2</sub> can change S1 only by 5%.  
And, what is most important, there no correlation between S1 and [O<sub>2</sub>].
- Changes in [N<sub>2</sub>] can explain 13% increasing of S1 light yield with time. For example, at t=0 [N<sub>2</sub>]~0.5ppm and at t=60 [N<sub>2</sub>]~0.1ppm.  
But is it possible to decrease [N<sub>2</sub>] if [O<sub>2</sub>] increases or doesn't changes?  
And, what is most important, why S1\_top and S1\_bottom have different dependencies with time?
- TPB dehydration can explain increasing of S1 light yield with time too. It can explain different dependencies of S1\_top and S1\_bottom with time.
- May be S2(purity corrected) vs time can clarify TPB or [N<sub>2</sub>] responsible for S1 changes.

Thank you for your attention!
