Introduction	Detection pipelines and sky localization	Ranking galaxies	EM follow up strategies	Conclusions
Introdu	iction			

- Success of the observational campaign following GW170817 originates also from some lucky coincidences: closest GW event and highest SNR.
- Skymap limited the 90% probability area to just  $28 \deg^2$ .
- Skymaps typically cover  $\mathcal{O}(100 1000) \text{ deg}^2$ .
- Ranking galaxies using gravitational information only could be helpful to astronomers.

# **Online** Pipelines

#### Modeled Search

- Search for specific signals from Compact Binary Coalescense
- GstLAL, MBTA, PyCBCLive, SPIIR
- matched-filtering based analysis

#### **Unmodeled Search**

- Core-collapse of massive stars, magnetar star-quakes, cosmic strings and others
- cWB, oLIB
- Excess power algorithms

<ロ > < 回 > < 目 > < 目 > < 目 > 目 の Q ( 3/16

<ロト < 回 ト < 三 ト < 三 ト 三 の へ ペ 4/16

# Matched Filtering

Given a signal  $s(t)=n(t)+h(t)\mbox{,}$  assuming Gaussian noise the log likelihood is given by

$$\ln \Lambda_h(t) = (s|h)(t) - \frac{1}{2}(h|h)(t)$$

where  $(a|b)(t) = 4\Re \int_0^\infty df \frac{\tilde{a}(f)\tilde{b}^*(f)}{S_n(f)}e^{-i2\pi ft}$ . Then, SNR time series for the single interferometer is

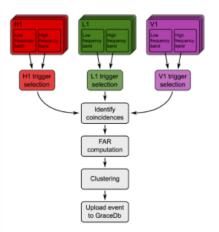

$$\rho_h^2(t) = 2\ln\Lambda_h(t)$$

Coincident SNR:

$$\rho_{coinc}^2 = \rho_i^2(t_i) + \rho_j^2(t_j)$$

### MBTA: Multi-Band Template Analysis

- Parameters space divided in 3 regions (approximately BNS, NSBH, BBH).
- Low-f and high-f bands with approximately equal SNR.
- Clusters triggers associated to the same event.

< □ > < □ > < Ξ > < Ξ > < Ξ > Ξ · の Q ↔ 5/16

#### Coherent SNR

Generalizing to many detectors<sup>1</sup>,  $\ln \Lambda_h(t) = (\mathbf{s}|\mathbf{h}) - \frac{1}{2}(\mathbf{h}|\mathbf{h})$  where  $(\mathbf{s}|\mathbf{h}) := \sum_{i=ifo} (s^i|h^i)$  and  $h^i(t) = \sum_{\mu=1}^4 \mathcal{A}^{\mu}(D, \psi, \phi_0, \iota) h^i_{\mu}(t)$ ,

$$\begin{split} h_1^i(t) &= F_+^i(\theta^i,\,\phi^i,\,\chi^i)h_0(t)\,,\\ h_2^i(t) &= F_\times^i(\theta^i,\,\phi^i,\,\chi^i)h_0(t)\,,\\ h_3^i(t) &= F_+^i(\theta^i,\,\phi^i,\,\chi^i)h_{\frac{\pi}{2}}(t)\,,\\ h_4^i(t) &= F_\times^i(\theta^i,\,\phi^i,\,\chi^i)h_{\frac{\pi}{2}}(t)\,. \end{split}$$

Then,

$$\ln \Lambda_h(t) = \mathcal{A}^{\mu}(\mathbf{s}|\mathbf{h}_{\mu}) - \frac{1}{2}\mathcal{A}^{\mu}\mathcal{M}_{\mu\nu}\mathcal{A}^{\nu}$$

with  $\mathcal{M}_{\mu\nu} := (\mathbf{h}_{\mu} | \mathbf{h}_{\nu})$ . Coherent SNR:

$$\rho_{coh}^2(t) = (\mathbf{s}|\mathbf{h}_{\mu})\mathcal{M}^{\mu\nu}(\mathbf{s}|\mathbf{h}_{\nu})$$

### Sky Localization and parameters estimation

- BAYESTAR: rapid CBC sky localization algorithm.
  - Coherently modeling the response of the gravitational-wave detector network.
  - Fixed masses and spins.
  - Computes the **posterior probability distribution** over the sky location and distance of the source.
  - Latency:  $\mathcal{O}(10)$  seconds.
- LALInference: full CBC parameter estimation algorithm.
  - Explores a greatly **expanded parameter space** (masses, spins...) with MCMC and nested sampling.
  - Performs **full forward modeling** of the gravitational-wave signal and the **strain calibration** of the gravitational-wave detectors.
  - Latency:  $\mathcal{O}(1)$  hours.

	Detection pipelines and sky localization	Ranking galaxies	EM follow up strategies	Conclusions
Strategy				

- Extract galaxies coordinates from Bayestar skymap.
- Select  $\mathcal{O}(10)$  templates that triggered in MBTA.
- Matched filtering of the two polarization already performed for online analysis.
- Compute the coherent SNR for each galaxy and for each template in the bank.
- Galaxy with higher cohSNR is the most likely to be the host.

# Querying galaxies with GWsky

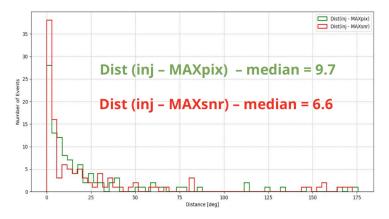

- **84** gravitational-wave sky localizations from the "First Two Years" paper<sup>2</sup> are selected (HLV).
- The **90% confidence level** for each probability skymap is build using the MOC (Multi Order Coverage map) implemented in GWsky/Aladin.
- We query databases for retrieving objects whose position falls within this MOC map at 90% confidence level using the **GLADE** catalog.
- We compute the sky position of the maximum probability pixel.
- See G. Greco's talk for more details.

#### <sup>2</sup>Singer et al. arXiv:1404.5623 [astro-ph.HE]

### Calculating the coherent SNR

- LALSuite code **lalapps\_cohPTF\_inspiral** looping over the selected galaxies from the GLADE catalog cutting at 1-sigma distance.
- Component masses of the **template with highest coincident SNR** are passed to a script that prepares a single-template bank that is used for the analysis.
- The template bank and the GPS times related to the each event are input of the function that computes the coherent SNR.

#### Large FoV telescopes

#### Small FoV telescopes

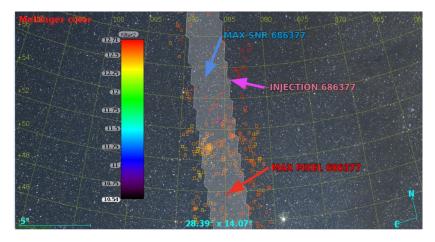

Figure: Here the injection is ranked 3rd using cohSNR while it is at the 41% c.l. that contains 285 galaxies.

Ranking galaxies

EM follow up strategies

Conclusions

### Small FoV telescopes

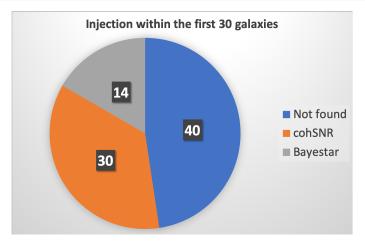

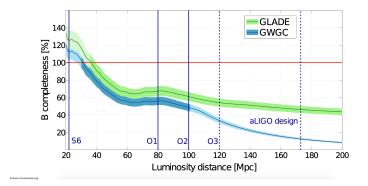

Figure: In 44/84 cases, either cohSNR or Bayestar capture the injection within the first 30 galaxies. In 15/44 cases both cohSNR and Bayestar rank the injection within the first 30 galaxies. cohSNR finds it in a higher ranking 11/15 times, and Bayestar 4/15 times.

# Conclusions & outlook

- Small template bank improved the results.
- Results are very **preliminary but intriguing** and motivate further investigation.
- More statistic is required.
- lalapps\_cohPTF\_inspiral is not optimised for our scope.
- EM-MBTA.py takes advantage of MBTA matched filtering output, computed for online detection.
- Expected latency of few minutes.

Introduction	Detection pipelines and sky localization	Ranking galaxies	EM follow up strategies	Conclusions
GLADE				

# Coincident and coherent SNR

#### coincident SNR

• Single IFO triggers in compatible time window

$$\rho_{coinc}^2 = \rho_i^2(t_i) + \rho_j^2(t_j)$$

- computationally cheap
- less information

#### coherent SNR

• coherence of phases and amplitudes in all IFOs

$$\rho_{coh}^2(t) = (\mathbf{s}|\mathbf{h}_{\mu})\mathcal{M}^{\mu\nu}(\mathbf{s}|\mathbf{h}_{\nu})$$

- computationally expensive
- more information
