#### 4 Results

Alberto Sciaccaluga

- AGN with a relativistic jet pointing toward the Earth
- The spectral energy distribution displays two broad peaks
- Blazars can be classified on the synchrotron peak frequency

### Blazar

- The second SED peak beyond 1 TeV
- A hard sub-TeV intrinsic spectrum
- The TeV emission is stable over years

- Low magnetization is required (see Biteau et al. 2020)
- Thermal plasma: recollimation shock + turbulence
- Non-thermal particles: diffusive shock acceleration + stochastic acceleration
- One zone Synchrotron Self Compton model

- Low magnetization is required (see Biteau et al. 2020)

## First attempt

# • Assumption: constant turbulence spectrum

- The rise in the sub-Tev range steeper than the data
- $t_{\rm damp}/t_{\rm cas} \sim \beta_a^{-1} U_e/U_B \ll 1$
- The turbulence damping is not negligible

- Assumption: constant turbulence spectrum
- The rise in the sub-Tev range steeper than the data
- $t_{\rm damp}/t_{\rm cas} \sim \beta_a^{-1} U_e/U_B \ll 1$
- The turbulence damping is not negligible

- Assumption: constant turbulence spectrum
- The rise in the sub-Tev range steeper than the data
- $t_{\rm damp}/t_{\rm cas} \sim \beta_a^{-1} U_e/U_B \ll 1$
- The turbulence damping is not negligible

Assuming isotropy and homogeneity (i.e. no spatial diffusion):

$$\begin{cases} \frac{\partial f}{\partial t} = \frac{1}{p^2} \frac{\partial}{\partial p} \left[ p^2 D_p \frac{\partial f}{\partial p} + p^2 \left( \frac{\partial p}{\partial t} \right)_{\text{rad}} f \right] + \frac{f}{t_{\text{esc}}} + I_f \\ \frac{\partial Z}{\partial t} = \frac{1}{k^2} \frac{\partial}{\partial k} \left( k^2 D_k \frac{\partial Z}{\partial k} \right) + \Gamma Z + \frac{I_W}{k^2} \quad \text{with} \quad Z = \frac{W}{k^2} \end{cases}$$

- We must solve a system of two coupled Fokker-Planck equations
- We decided to use the robust implicit Chang-Cooper algorithm
- Kolmogorov phenomenology  $\implies D_k = D_k(k, W) \implies$  Non-linearity
- We need a trick (see Larsen et al. 1985)

## 1ES 0229+200

We apply our model to the prototypical extreme TeV BI Lacs, i.e. 1ES 0229+200

- Downstream region radius  $R = 1.2 \times 10^{16}$  cm
- Alfvén velocity  $v_a = 2 \times 10^9 \text{ cm/s}$
- Mean magnetic field B = 15.9 mG
- Injected electrons power  $P'_n = 7 \times 10^{39} \text{ erg/s}$
- Injected turbulence power  $P'_W = 7 \times 10^{39} \text{ erg/s}$

The electrons spectrum and the energy peak increase until the cooling becomes relevant. The final spectrum presents the following features:

The turbulence cascades to larger wavenumbers until the electrons damping becomes relevant. The final spectrum presents the following features:

• Cut-off at 
$$k \gtrsim 10^{-10} \text{ cm}^{-1}$$
  
• Power law at  $k \lesssim 10^{-10} \text{ cm}^{-1}$   
• Power law at  $k \lesssim 10^{-10} \text{ cm}^{-1}$   
• Power law at  $k \lesssim 10^{-10} \text{ cm}^{-1}$ 

Our model was able to reproduce the SED of the prototypical extreme TeV BI Lacs 1ES 0229+200  $\,$ 

- Caveats
  - Necessary comparison with other SEDs
  - Check with MHD simulations
- Improvements
  - Addition of IC cooling term (other non-linear term)
  - More accurate algorithm (e.g. Runge-Kutta Implicit-Explicit schemes)
