

# The BPS limit of AdS black hole thermodynamics and its microscopic counterpart

*Tuesday, October 22, 2019 9:00 AM (35 minutes)*

The talk will present progress towards a microscopic understanding of the entropy of rotating BPS black holes in AdS. I will describe a new BPS limit of black hole thermodynamics which first focuses on a supersymmetric family of complexified solutions and then reaches extremality. In this limit the chemical potentials obey a constraint that is interpreted as a regularity condition in the Euclidean bulk geometry, and the on-shell gravitational action, which is the grand-canonical counterpart of the Bekenstein-Hawking entropy, takes a very simple form. I will then focus on AdS<sub>5</sub> black holes, where the gravitational analysis instructs us that the holographic dual N=1 superconformal field theory is defined on a twisted  $S^1 \times S^3$  with complexified chemical potentials obeying the constraint, and localization allows to compute the partition function exactly. This computation defines a slightly modified superconformal index as well as a generalization of the supersymmetric Casimir energy. I will discuss how the black hole entropy is encoded in these quantities.
