ML/DL in HEP

D. Bonacorsi (University of Bologna)

Corso CCR Big Data - Bologna, 9-13 September 2019

High Energy Physics (HEP)

HEP focus is the study of **fundamental interactions** among **elementary particles**

- quarks and leptons as building blocks
- aiming at a complete understanding of *microcosm* and *macrocosm*

HEP physicists **create matter**

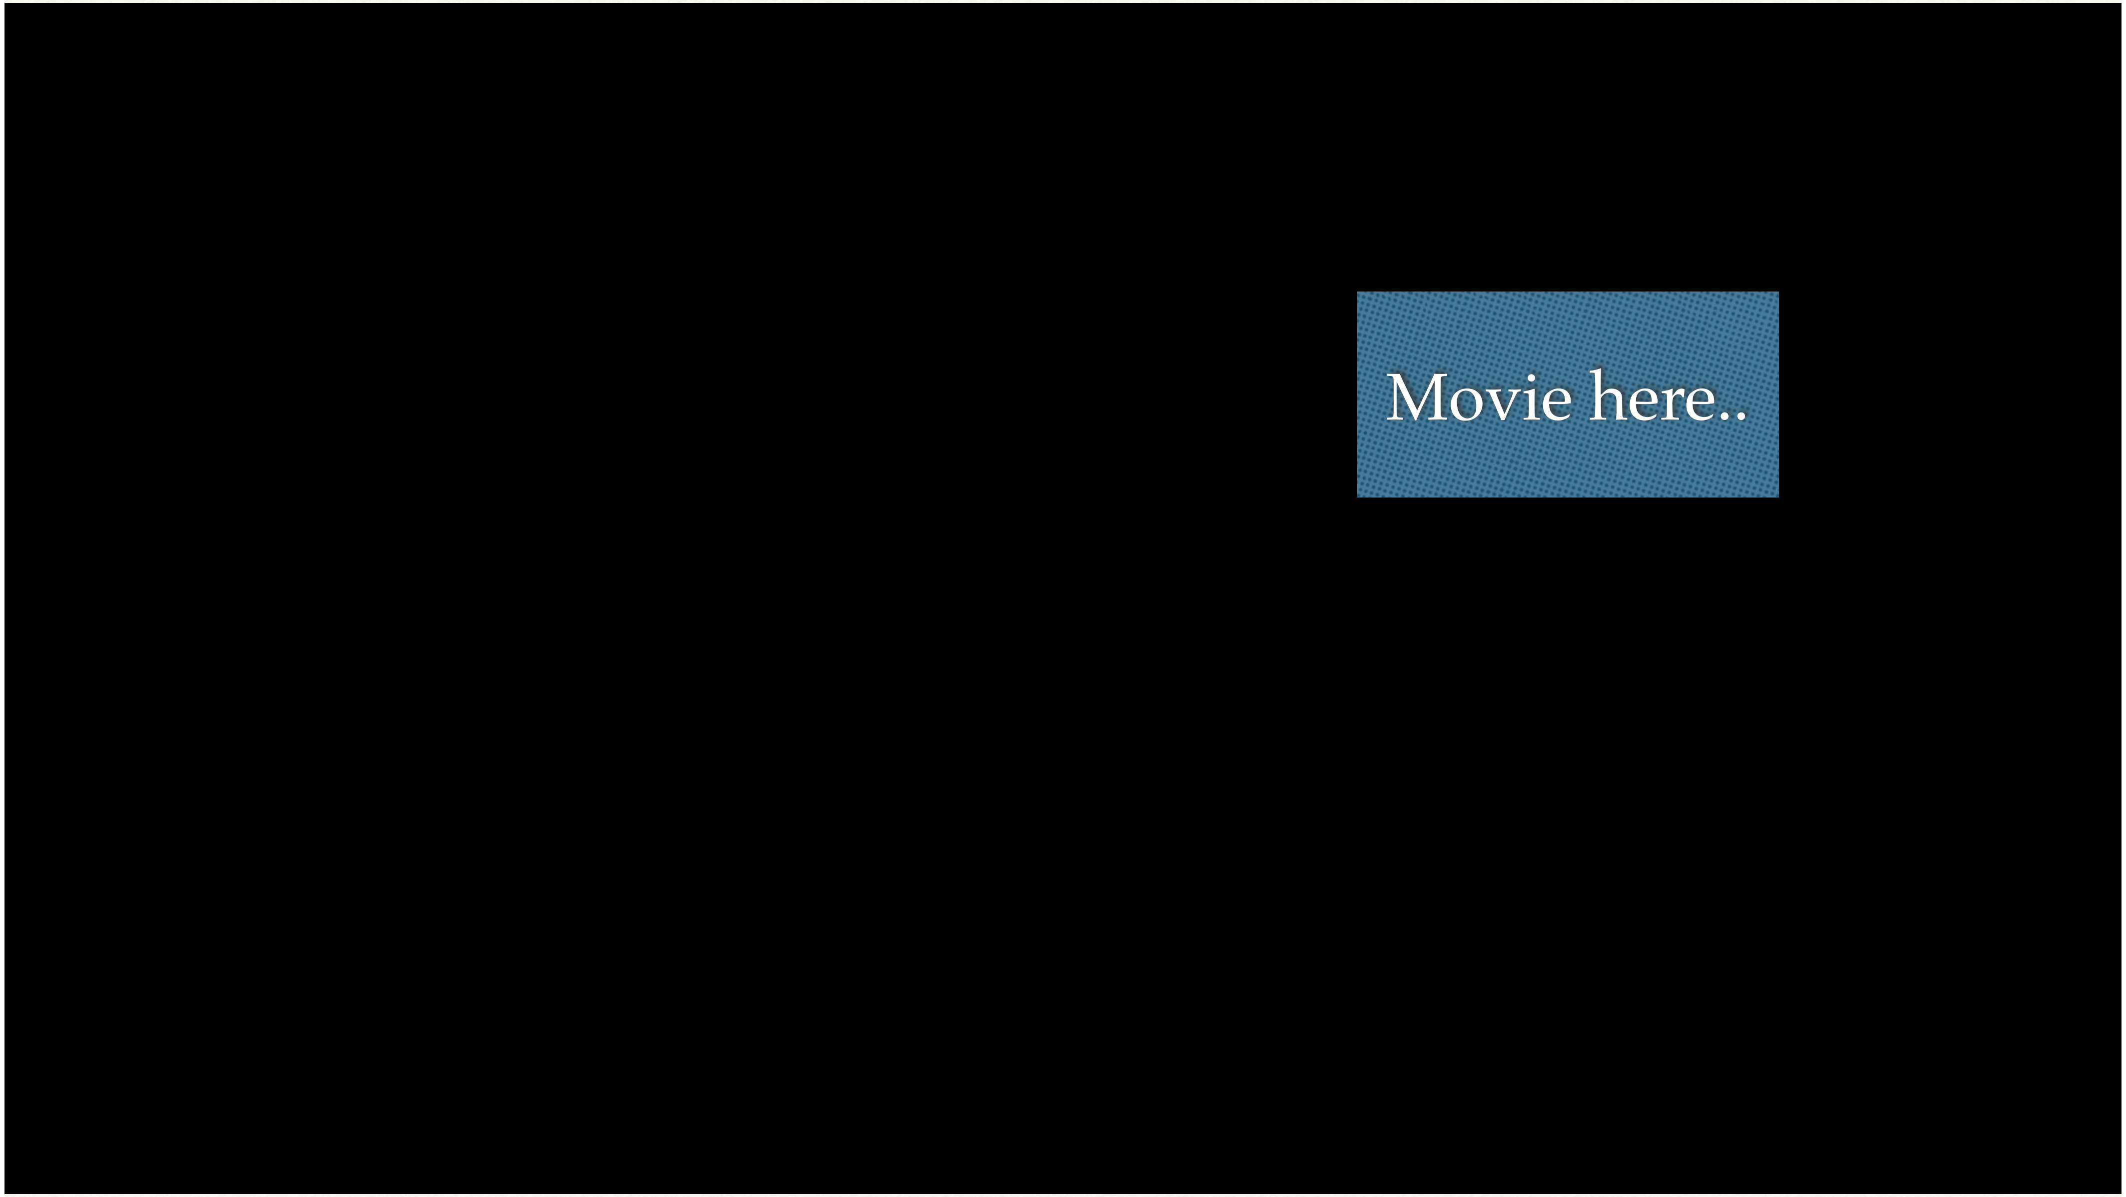
- they need to observe and study it beyond the ordinary one, hence they create matter in the states it existed fractions of seconds after the Big Bang

HEP physicists' instruments are **particle accelerators** plus large and complicated **particle detectors** around interaction points

- build and operate accelerators, accelerate particles to collisions, measure fragments that fly through the active volumes of the detectors → physics!
- or - in the case of Astrophysics - the Universe is a "natural particle accelerator"

This is amazingly fascinating and beautiful. And so complicated..

HEP with LHC at CERN



Innovation is hard(er in Big Science)

HEP community is **at the frontier of computing technologies**

- (apart from the obvious WWW born at CERN..) HEP has driven Grid Computing worldwide

But HEP community is extremely **large**, work on **long timescales**, and some **inertia** in a otherwise flexible adoption of new paradigms can be observed

- Current generation experimental programmes last *decades*. Long planning, long construction time, long operation by huge collaborations (~1000s of scientists)

Software and Computing experts from previous generation of experiments **pioneered studies employing ML** and laid the ground for the emergence of ML as an essential tool for HEP

But HEP timescales are <u>decades</u>, while ML/DL evolution timescale is <u>years</u> (or less..).

Today, important focus is in cross-discipline fertilisation (cultural and technical)

- Incorporating the "latest greatest" new ML/DL tools in experiments that are finally taking data after decades of construction and large investments.. while maintaining the scientific rigour required in particle physics analyses.. in such a huge scientific environment.. all this presents some unique (not only technical!) challenges and opportunities

Which ML for HEP

Very wide use of **supervised ML** (mostly)

- e.g. training algorithms to classify data as signal or background by studying existing labeled (possibly Monte Carlo) data.

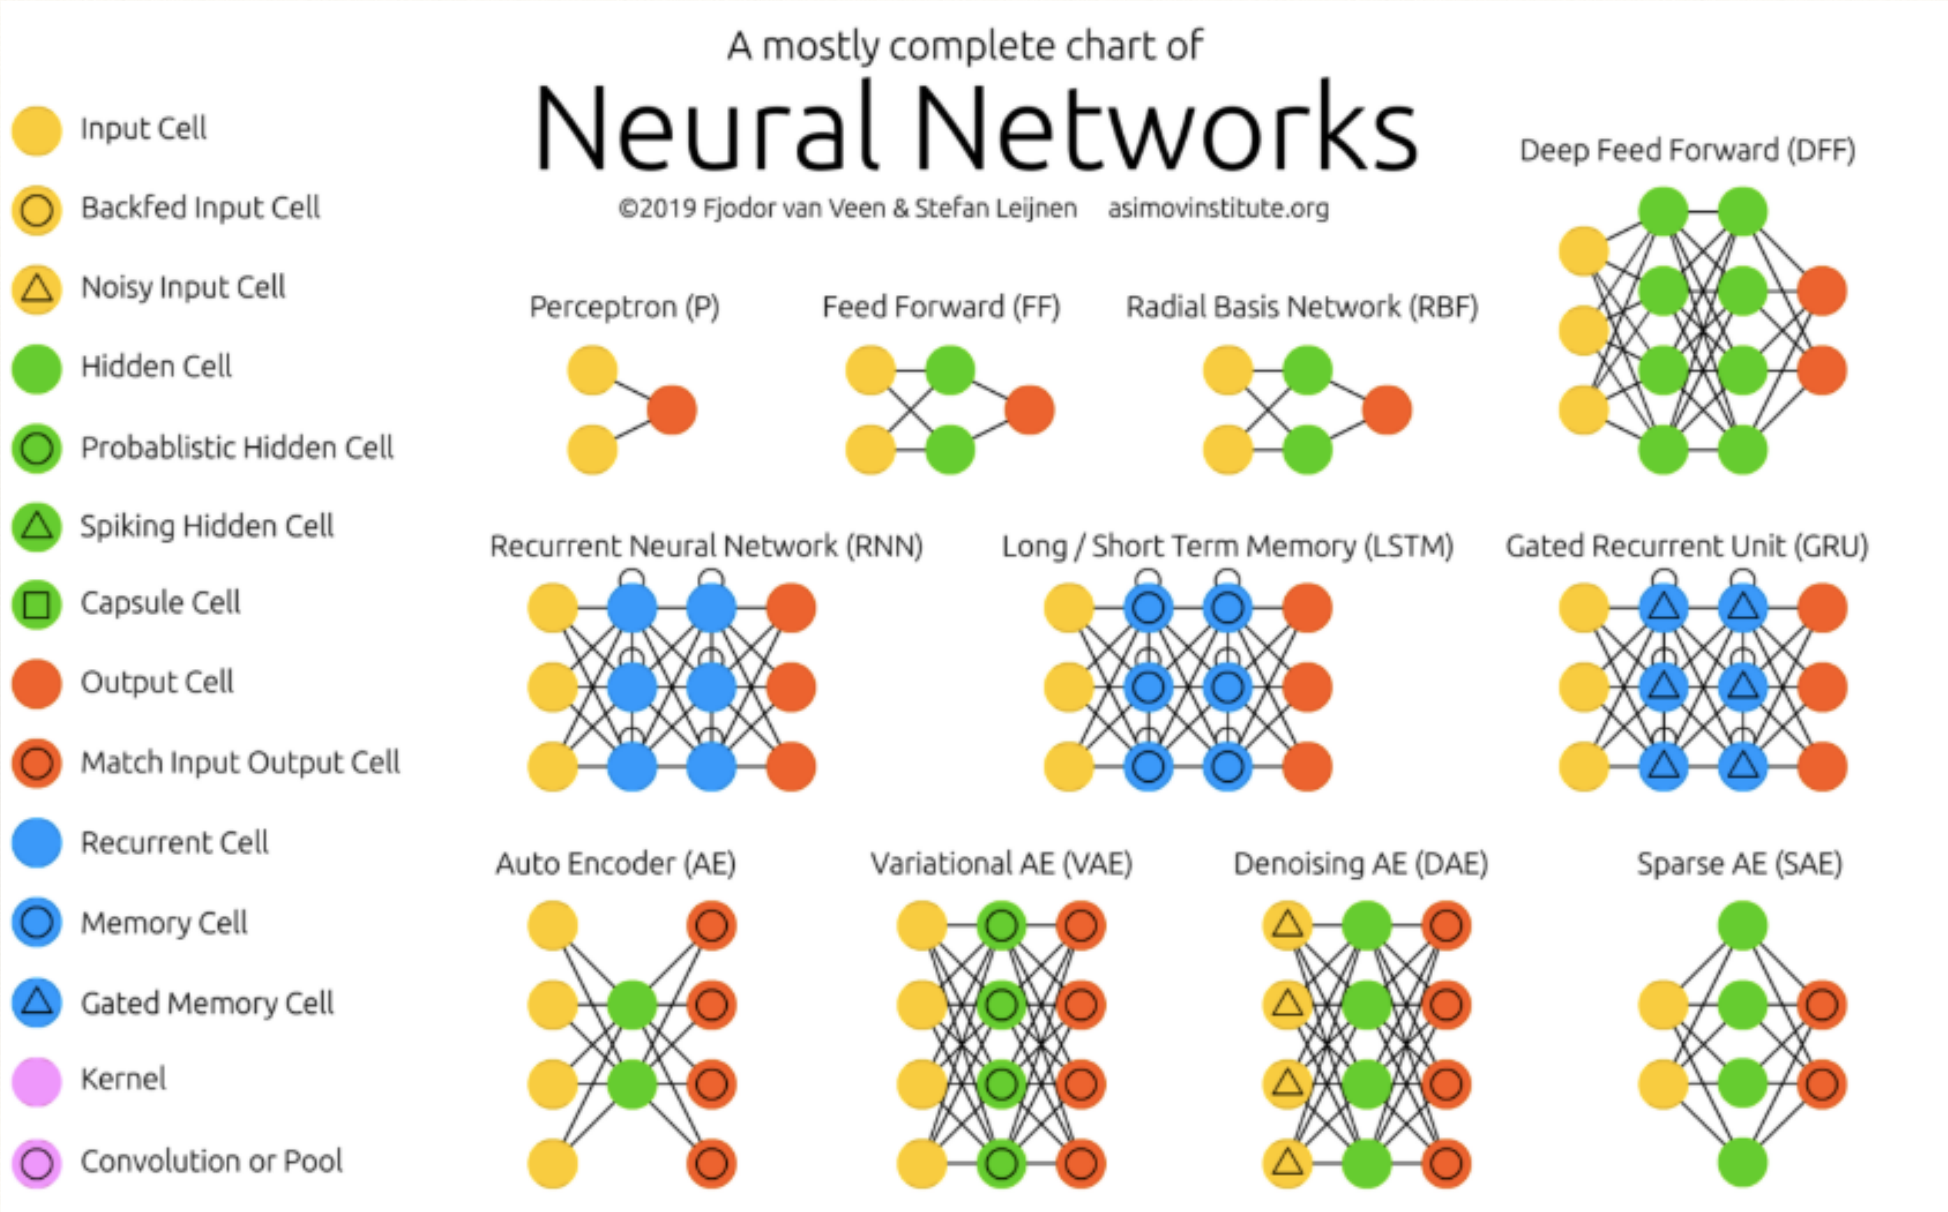
Typical *ML workflow* in HEP? (simplified..)

- problem statement and data preparation: variables relevant to the physics problem are selected, data are cleansed, etc
- training: e.g. a ML model is trained for *classification* using signal and background events (the most human- and CPU- time consuming)
- inference: relatively inexpensive

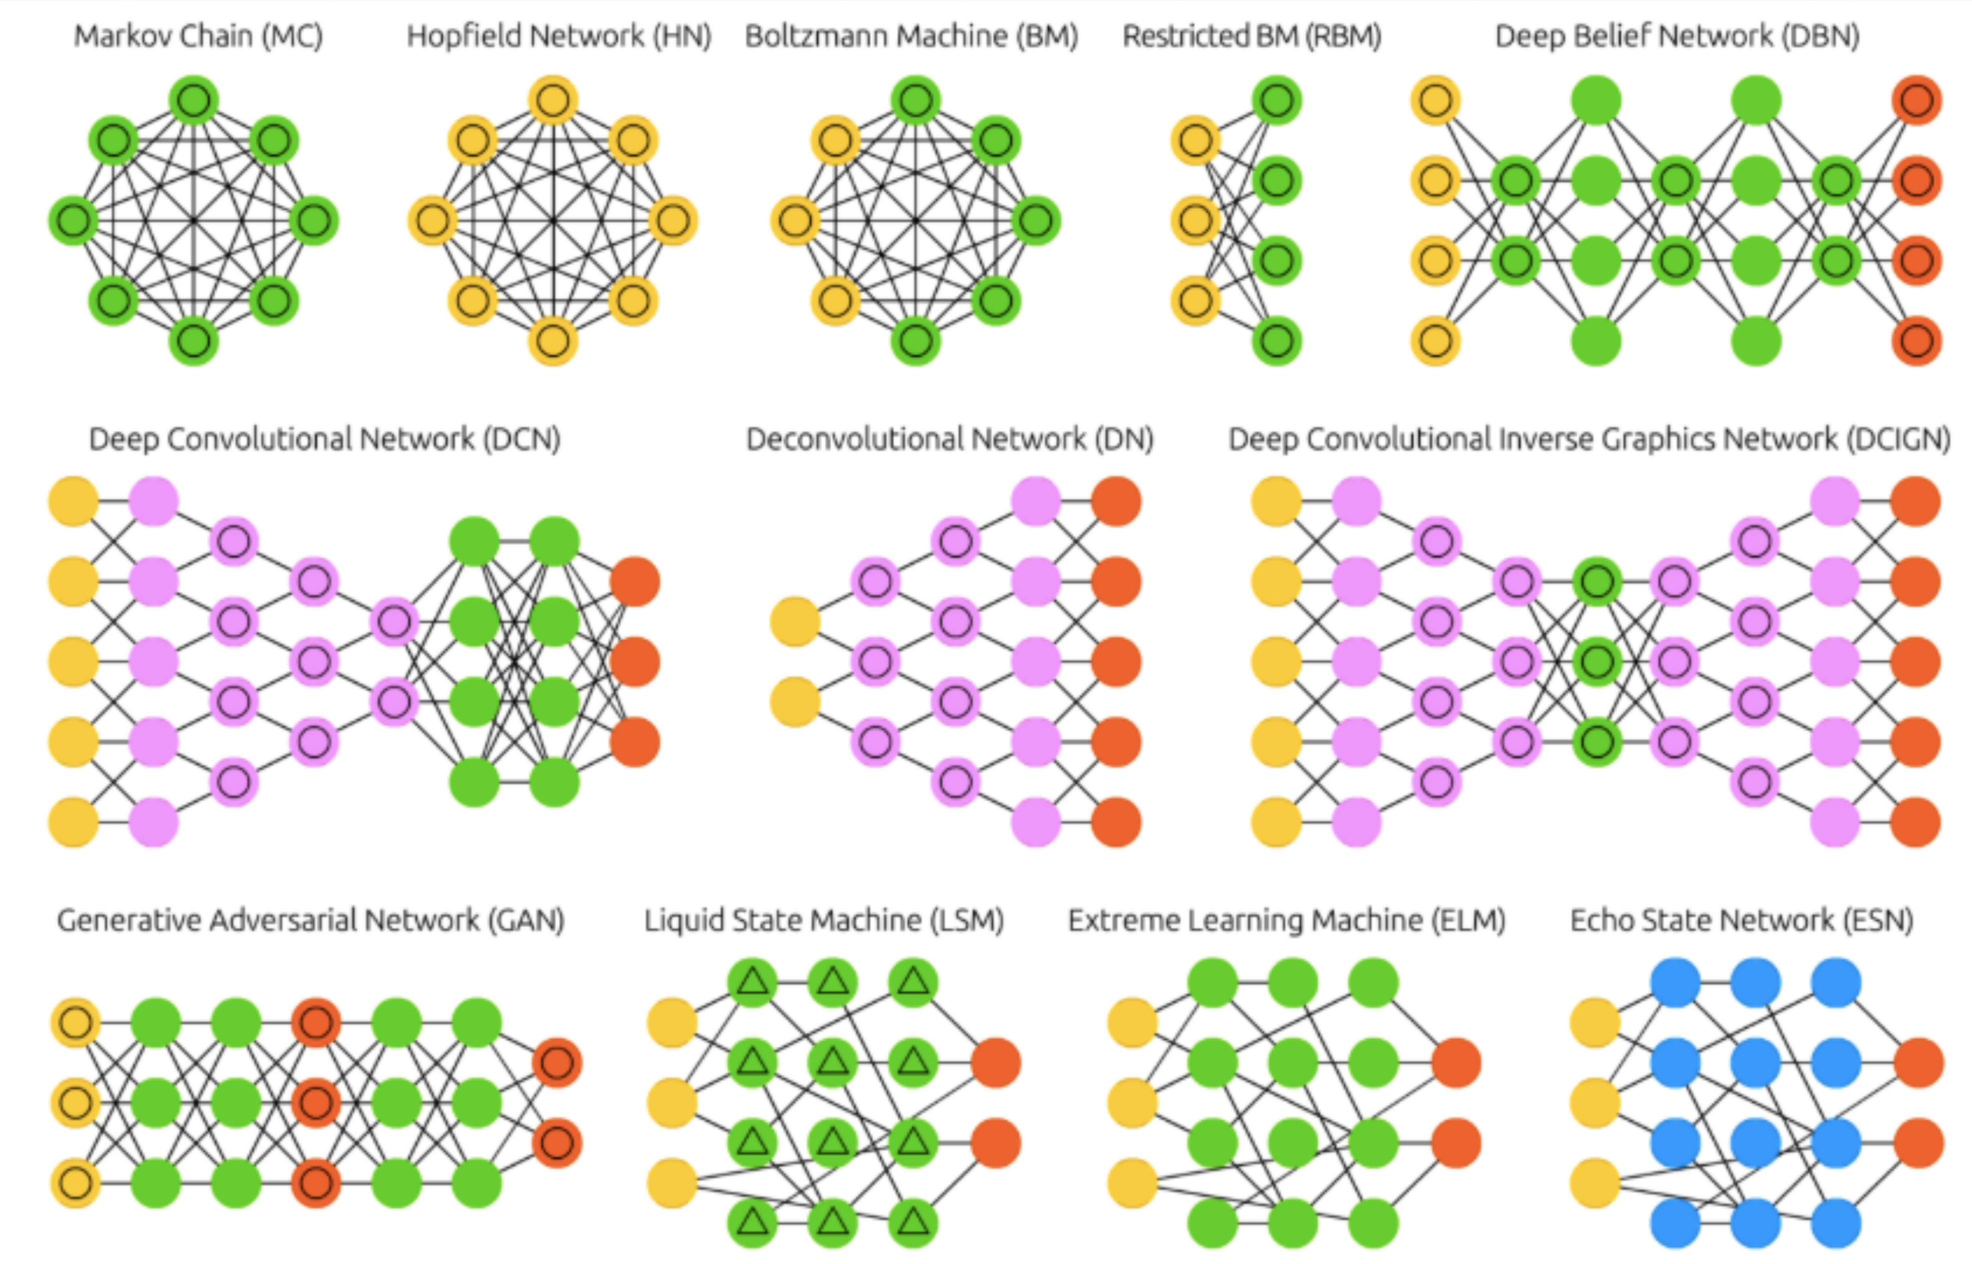
Typical *ML algorithm* for HEP?

- a large plethora of categories of algorithms to even attempt to list them ..
- mostly: Boosted Decision Trees (**BDT**s) and Artificial Neural Networks (**ANN**s)
- then, expanding from these to more..

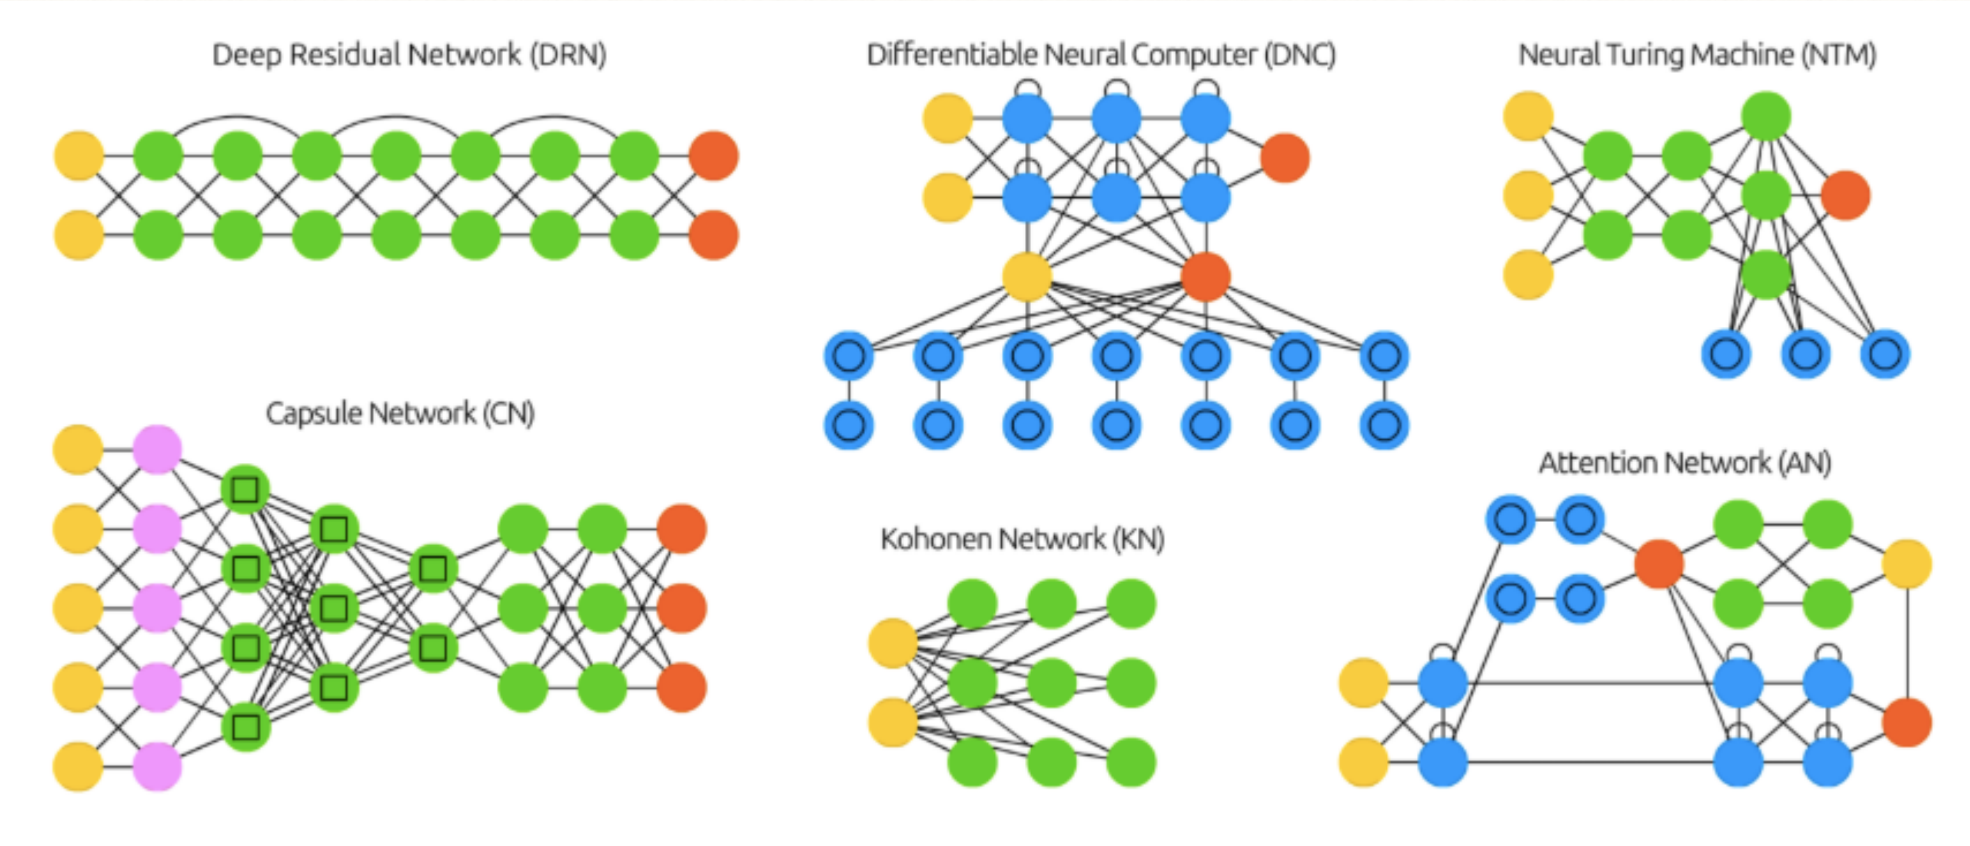
asimovinstitute.org [1/3]



asimovinstitute.org [2/3]



asimovinstitute.org [3/3]



More on ML algorithms in HEP

BDTs/**ANN**s typically used to classify particles and events

- they are also used for regression, e.g. to obtain the best estimate of particle's energy based on the measurements from several detectors

ANNs being used for a while in HEP, then.. → rise of **DNN**s

- particularly promising when there is a large amount of data and features, as well as symmetries and complex non-linear dependencies between inputs and outputs

Different types of NNs used in HEP:

- fully-connected (**FCN**), convolutional (**CNN**), recurrent (**RNN**) network
- additionally, NNs are used in the context of Generative Models, when a NN is trained to mimic multidimensional distributions to generate any number of new instances. Variational AutoEncoders (**VAE**s) and more recent Generative Adversarial Networks (**GAN**s) are two examples of such generative models used in HEP.

Plus, ML algorithms devoted to <u>time-series analysis</u> and prediction

- in general not relevant for HEP where events are independent from each other
- however, growing interest in these algorithms for HEP-related sequential non-collision data, e.g. for Data Quality and Computing Infrastructure monitoring (as well as those physics processes and event reconstruction tasks where time is an important dimension)

HEP as ML consumers, not producers

At a first approximation, most ML usage in HEP is <u>not</u> ML research

- HEP community is being building domain-specific applications on top of existing toolkits and ML algorithms developed by computer scientists, data scientists, and scientific software developers from outside the HEP world

Work is also being done to understand where HEP problems do not map well onto existing ML paradigms and how these problems can be recast into abstract formulations of more general interest

Frameworks and tools

Vast majority of *HEP-physicists* (end-users, i.e. data analysts) nowadays mostly use TMVA in ROOT.

Non-HEP scientists (and not scientists, too) use e.g.:

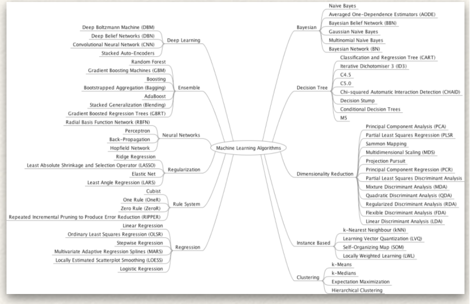
HEP community now **more and more open to the worldwide approach to ML**

Opportunities and challenges



Abundance: the number of ML algos and implementations in a growing variety of frameworks and libraries

- drawback: difficult and time-consuming to evaluate tradeoffs for using one ML "tool" compared to another, and also tradeoffs for ML vs non-ML solutions

Advancement: extremely quick

- drawback: HEP research teams need to investigate the numerous approaches at hand, adequate skills are needed to follow up, complexity requires not-best-effort engagements

Open-source and code accessibility, documentation, training: the portfolio of ML techniques and tools is in constant evolution, many have well-documented open source software implementations, often supported by MOOCs, etc

- drawback: acquired expertise and lessons learned by few people risks to get lost before being adequately disseminated to a wider community + issues in adequate training of young HEP collaborators

Hype: guarantees attention and investments

- drawback: overhyped?!

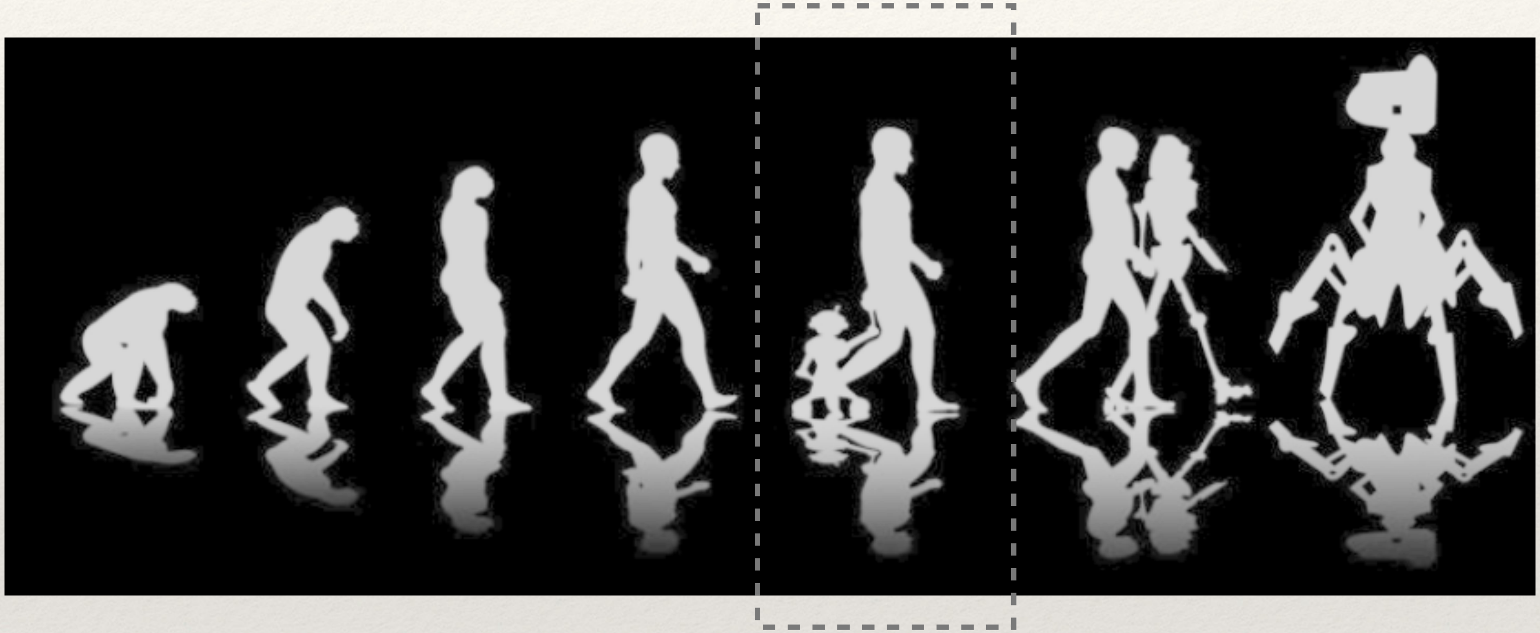
Up to now..



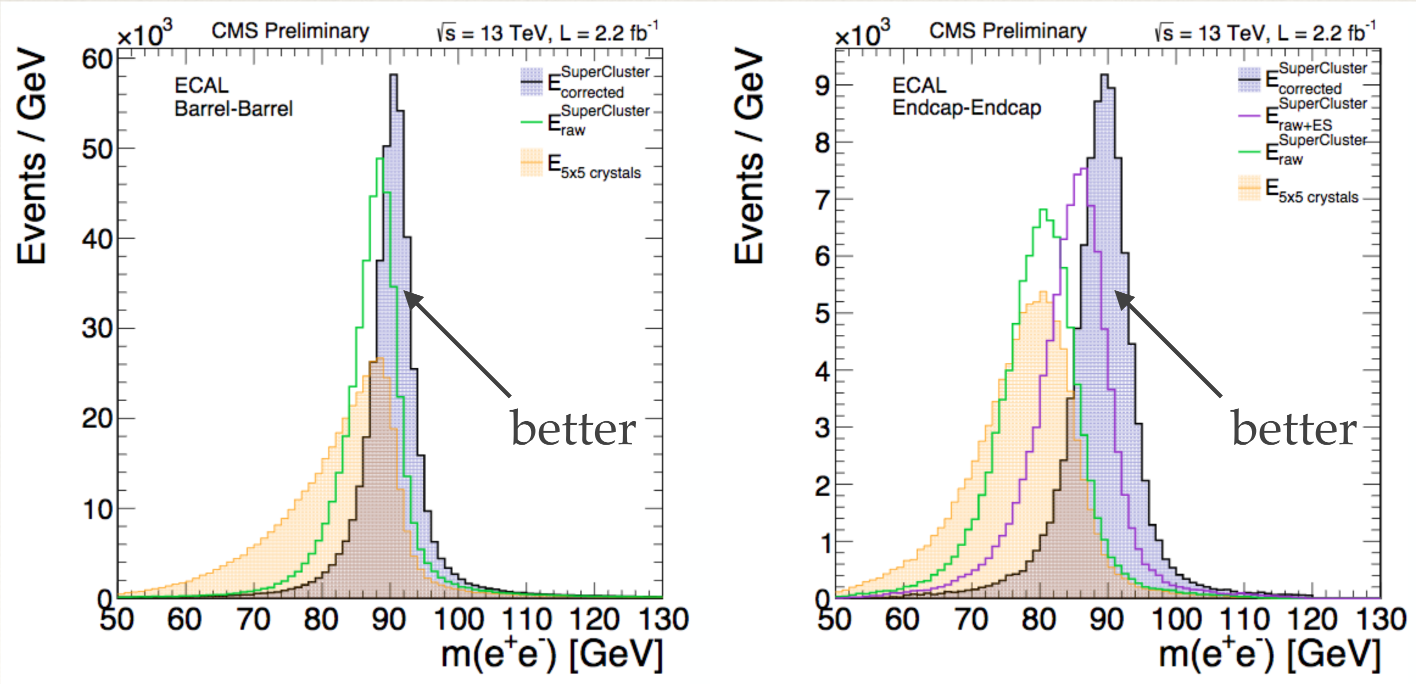
ML in HEP as the use of field-specific knowledge for feature engineering

i.e. use physicist-designed high-level features as input to shallow algorithms

Particle properties: energy resolution

Using ML to improve the determination of particle properties is now commonplace in **all LHC experiments**

- E.g. energy deposited in calorimeters is recorded by many sensors, which are clustered to reconstruct the original particle energy. **CMS** is training **BDT**s to learn corrections using all information available in the various calorimeter sensors - thus resulting in a <u>sizeable improvement in resolution</u>



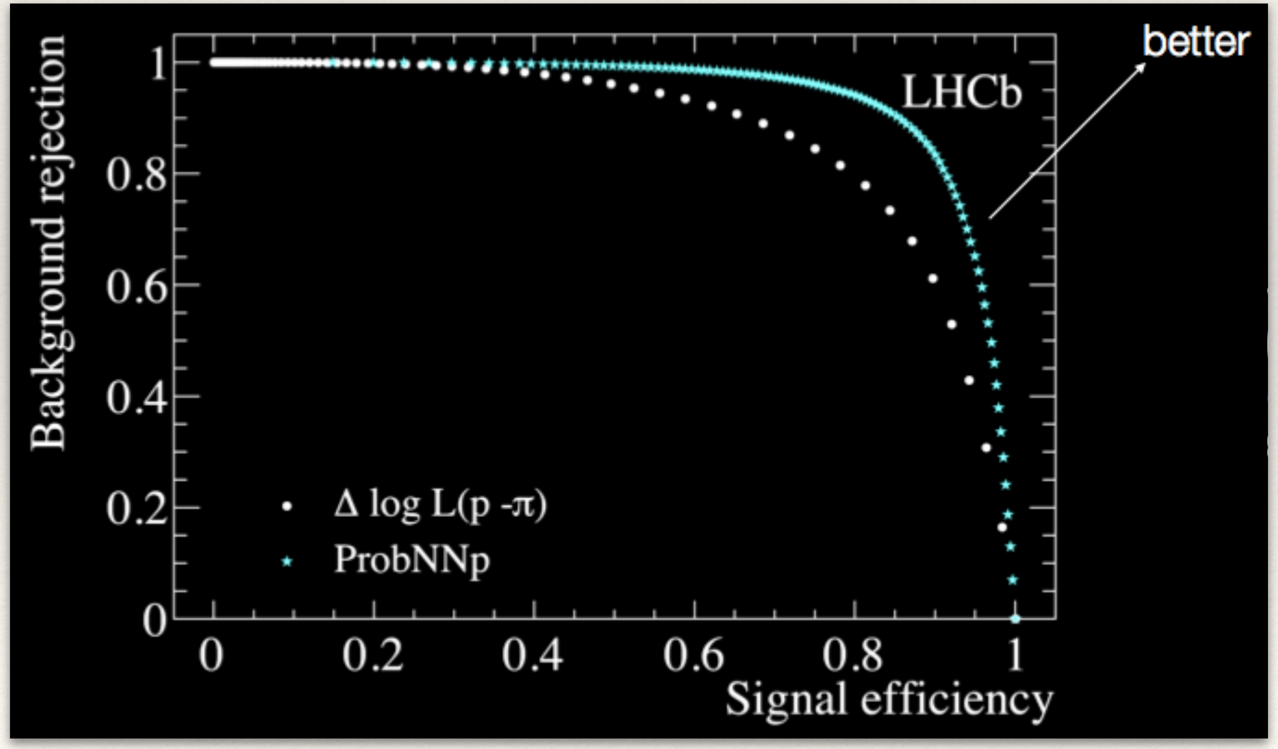
Improvements to the Z→e+e- energy scale and resolution from the incorporation of more sophisticated clustering and cluster correction algorithms (energy sum over the seed 5x5 crystal matrix, bremsstrahlung recovery using supercluster, inclusion of pre-shower energy, **energy correction using a multivariate algorithm**)

[2015 ECAL detector performance plots, <u>CMS-DP-2015-057</u>. Copyright CERN, reused with permission]

Particle ID

Similarly, ML is commonly used to identify particle types

- e.g. **LHCb** uses **NN**s trained on O(30) features from all its subsystems, each of which is trained to identify a specific particle type
- ~3x less mis-ID bkg /particle. Estimates indicate that more advanced algorithms may reduce bkg by another ~50%

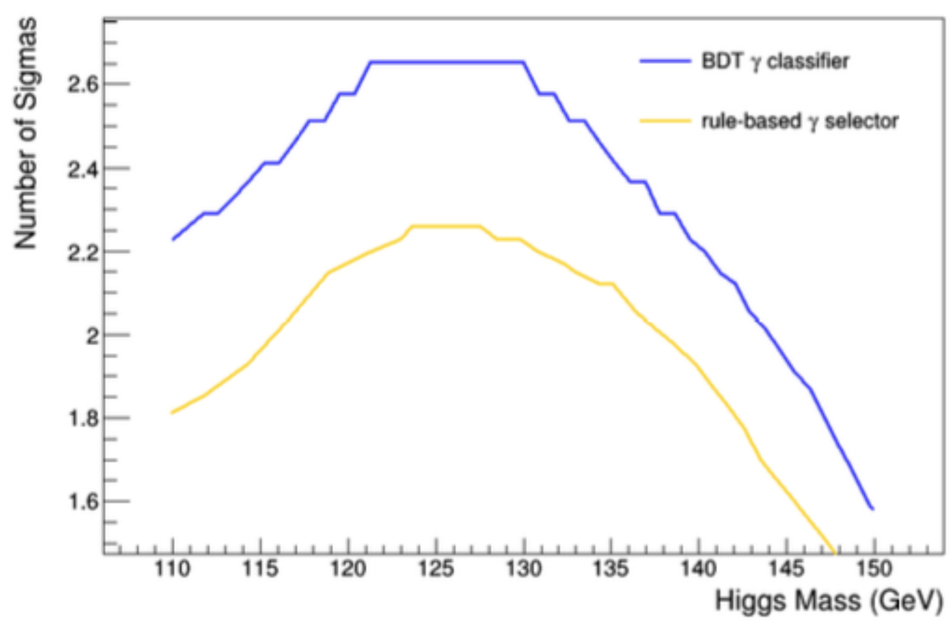


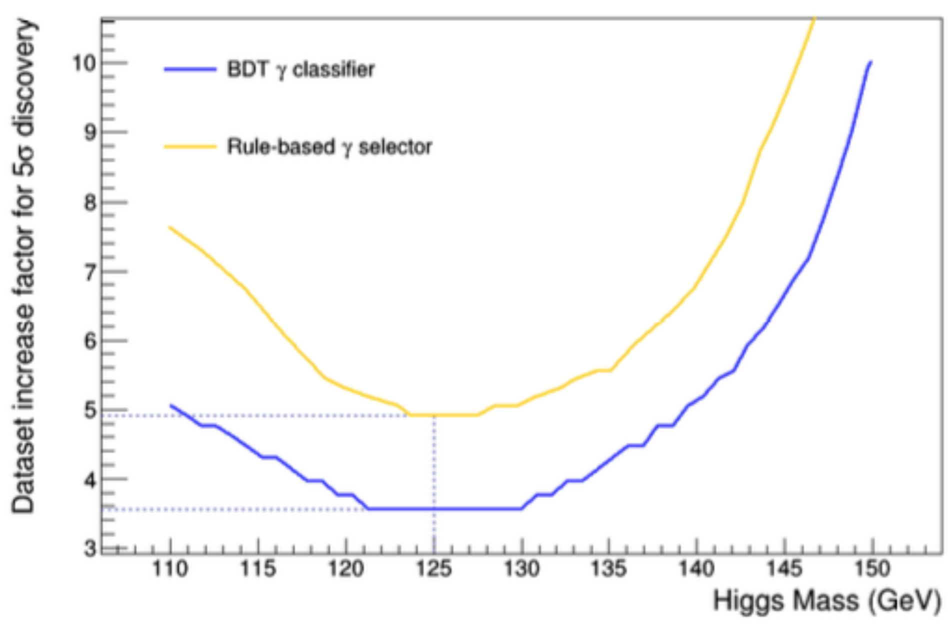
[courtesy: M.Williams]

Discovery of the Higgs boson

ML played a key role in the discovery of the Higgs boson, especially in the diphoton analysis by **CMS** where ML (used to improve the resolution and to select/categorize events) increased the sensitivity by roughly the equivalent of collecting ~50% more data.

[courtesy M.Pierini]





We were not supposed to discover the Higgs boson as early as 2012

- **Given how machine progressed, we expected discovery by end 2015 / mid 2016**

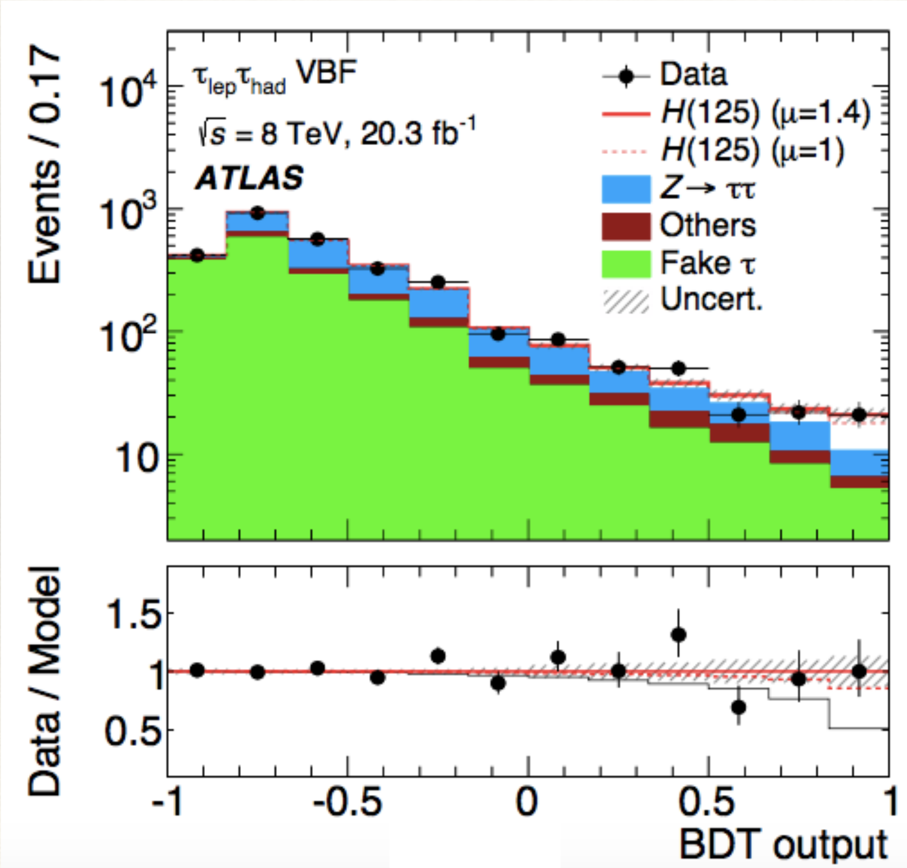
We made it earlier thanks (also) to ML

Study of Higgs properties

E.g. analysis of τ leptons at LHC complicated as they decay before being detected + loss of subsequently produced neutrinos + bkg from Z decays

- e.g. **ATLAS** divided the data sample into 6 distinct kinematic regions, and in each a **BDT** was trained using 12 weakly discriminating features → improved sensitivity by ~40% vs a non-ML approach

Also part of the 2014 Higgs ML **Kaggle** challenge

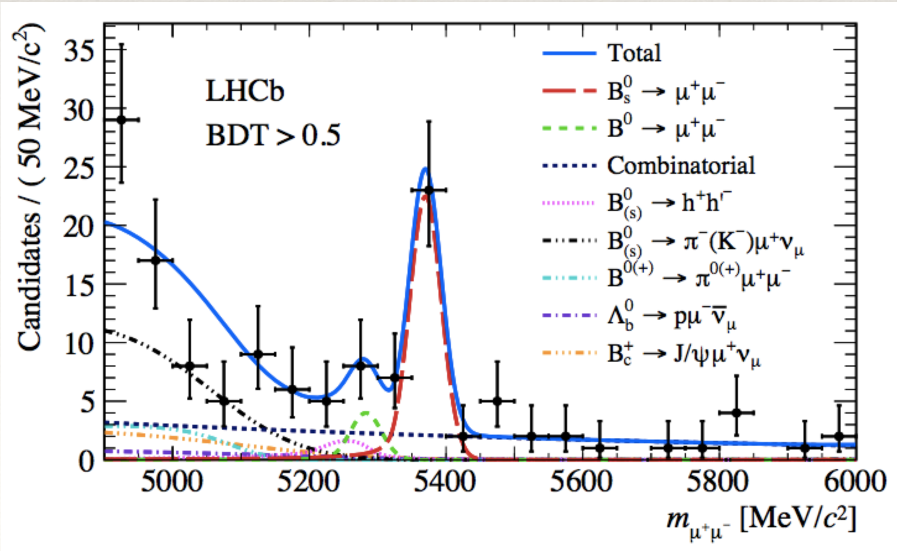


[arXiv:1501.04943]

High-precision tests of the SM

CMS and **LHCb** were the first to find evidence for the $B^0_s \to \mu^+\mu^-$ decay with a combined analysis (as rare as ~ 1 / 300 billion pp collisions..)

- **BDT**s used to reduce the dimensionality of the feature space - excluding the mass - to 1 dimension, then an analysis was performed of the mass spectra across bins of BDT response
- decay rate observed is consistent with SM prediction with a precision of ~25%, placing stringent constraints on many proposed extensions to the SM
- To obtain the same sensitivity without ML by LHCb as a single experiment would have required ~4x more data. Just one of many examples of high-precision tests of the SM at the LHC where ML can dramatically increase the power of the measurement



Mass distribution of the selected $B^0 \to \mu^+\mu^-$ candidates with BDT > 0.5.

[arXiv: 1703.05747]

Trigger

Crucial trade-off in algorithm complexity and performance under strict inference time constraints

E.g. **ATLAS/CMS** each only keep about 1 in every 100 000 events, and yet their data samples are each still about 20 PB/yr

- ML algorithms have already been used very successfully for rapid event characterisation
- adoption depth vary across experiments, but the increasing event complexity at HL-LHC will require more sophisticated ML solutions and its expansion to more trigger levels

A critical part of this work will be to understand which ML techniques allow us to maximally exploit future computing architectures

Trigger (cont'd)

E.g. **CMS** employs ML in its trigger hardware to better estimate the momentum of muons

- inputs to the algorithm are discretised to permit encoding the ML response in a large look-up table that is programmed into FPGAs

E.g. **LHCb**, many of the reactions of greatest interest do not produce striking signatures in the detector, making it necessary to thoroughly analyse high-dimensional feature spaces in real time to efficiently classify events

- LHCb used a **BDT** for 2 years, then a MatrixNet algorithm
- ML now almost ubiquitous in LHCb Trigger. 70% of all persistent data is classified by ML algorithms. All charged-particle tracks are vetted by **NN**s.
- LHCb estimated that <u>reaching the same sensitivity as a recent LHCb search for the dark matter on 2016 data, would have required collecting data for 10 yrs without the use of ML</u>

Tracking

Pattern recognition has always been a computationally challenging step

- e.g. the HL-LHC environment makes it an extremely challenging task

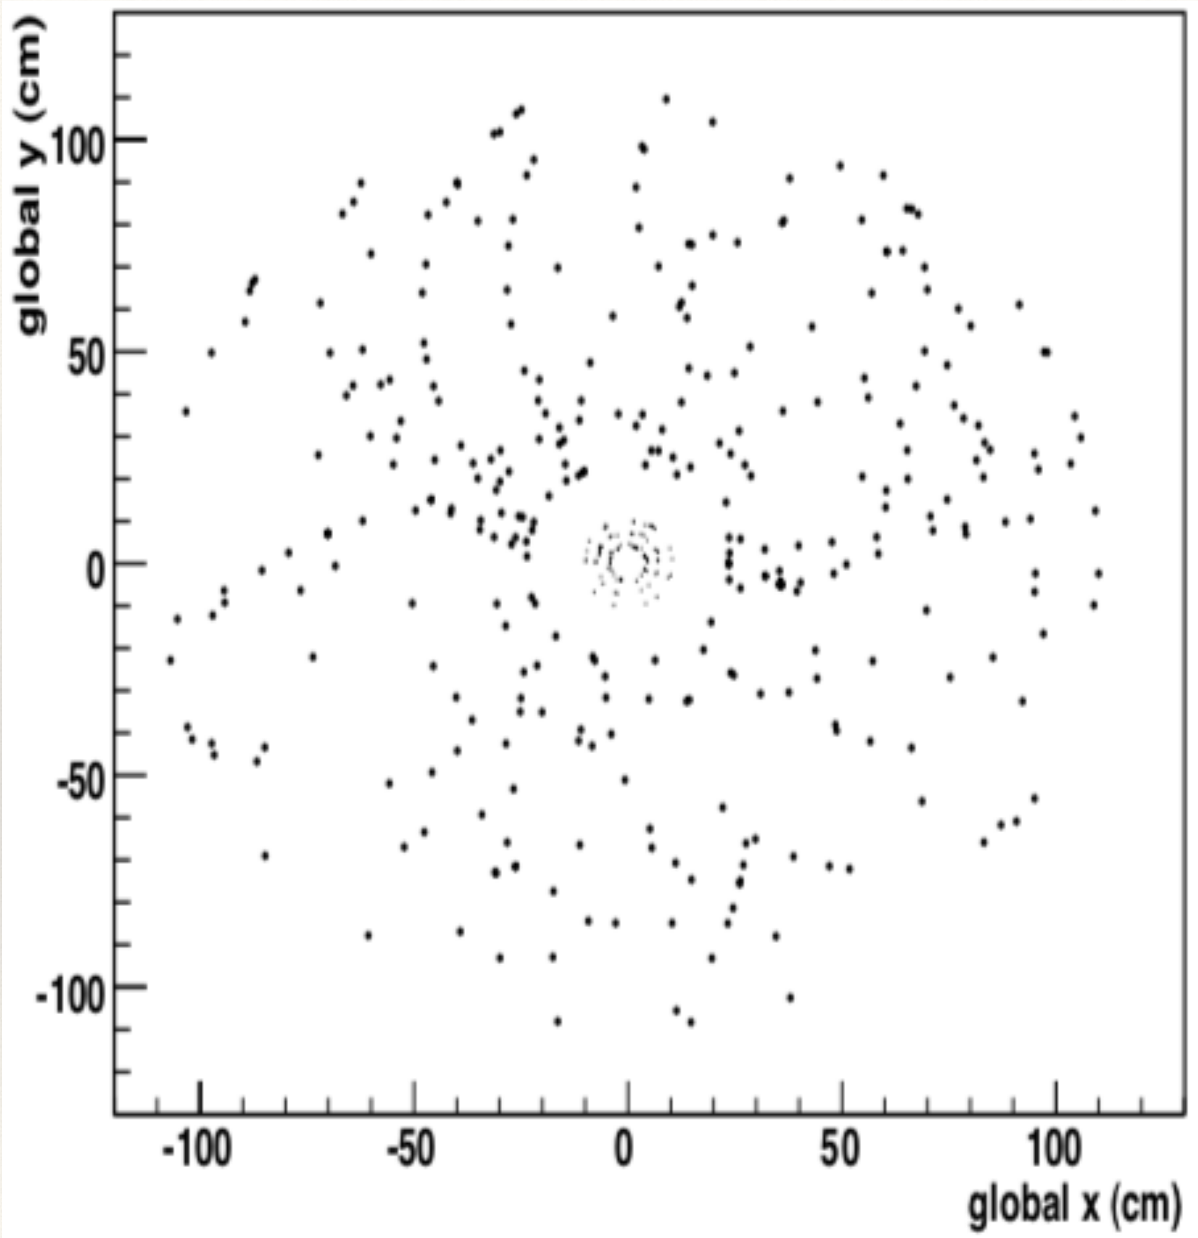
Adequate ML techniques may provide a solution that scales linearly with LHC intensity.

Several efforts in the HEP community have started to investigate sophisticated ML algorithms for track pattern recognition on many-core processors.

No time to cover all this area in details..
just a few plots to highlight the complexity of the task

Challenge **yourself** as a tracking system

Can you find a high momentum particle?



<u>Hint</u>: charged particles travel in helical paths, with the radius of the helix proportional to the particle momentum

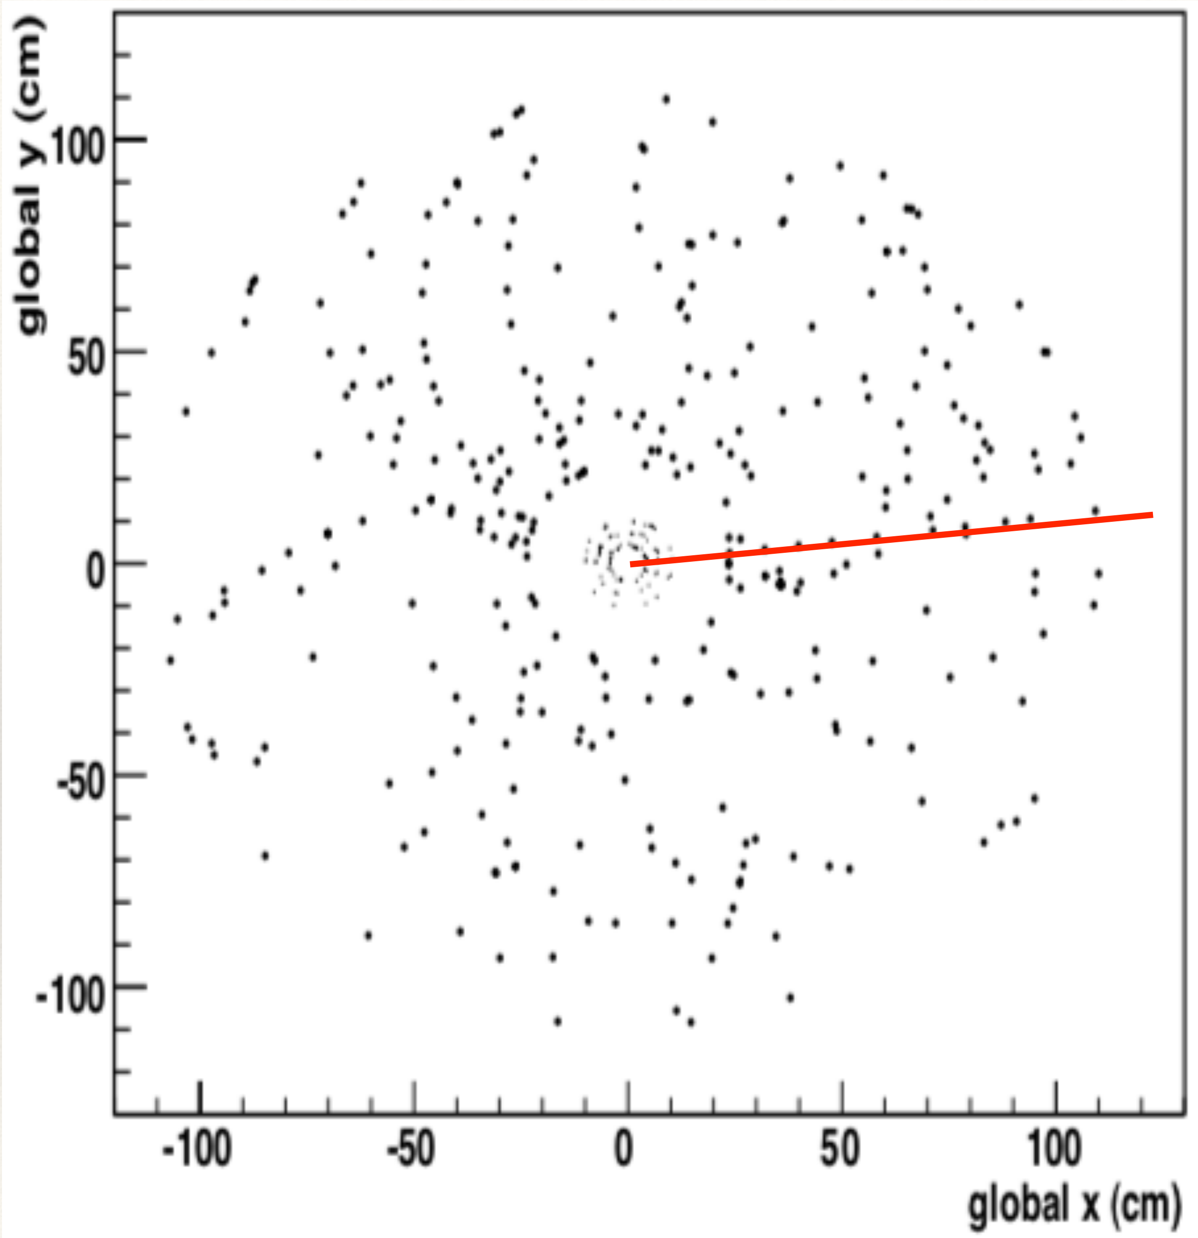
Challenge **yourself** as a tracking system

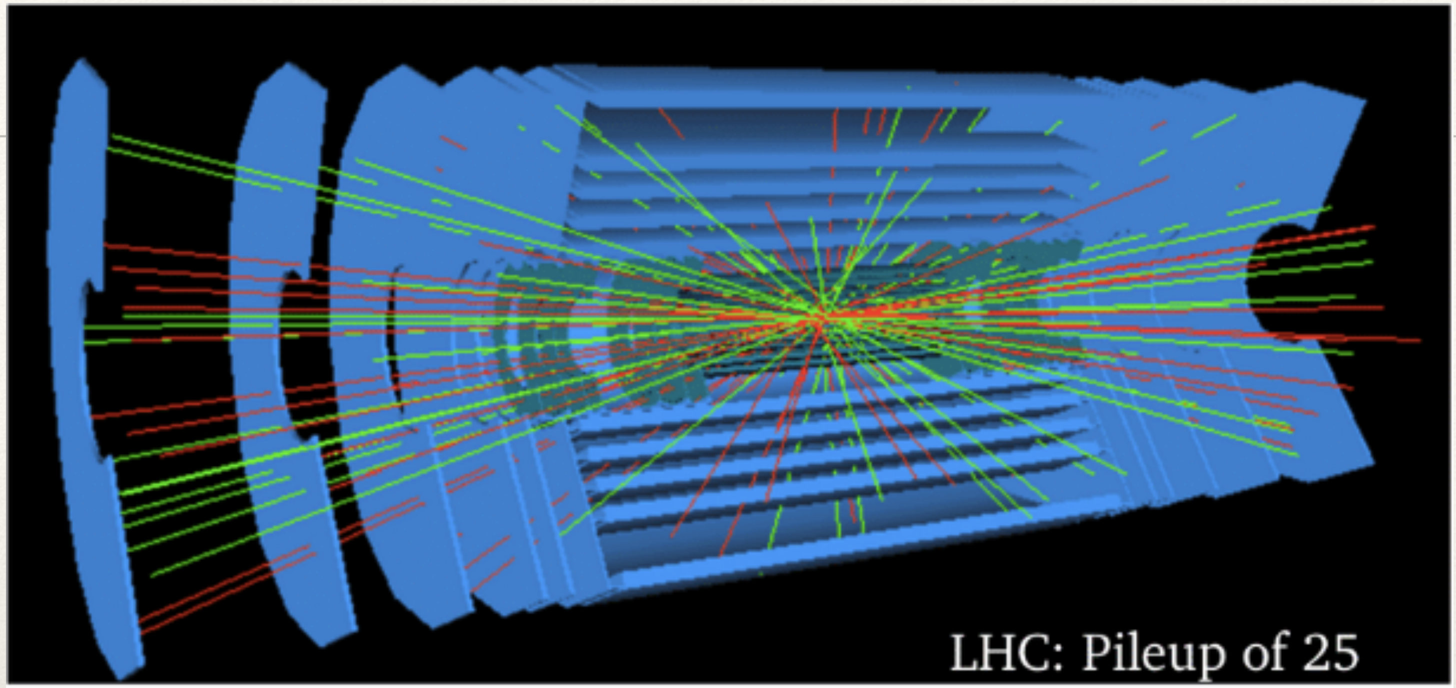
Can you find a high momentum particle?

Track finding (a pattern recognition problem) is one of the most computationally intense event reconstruction problems we have

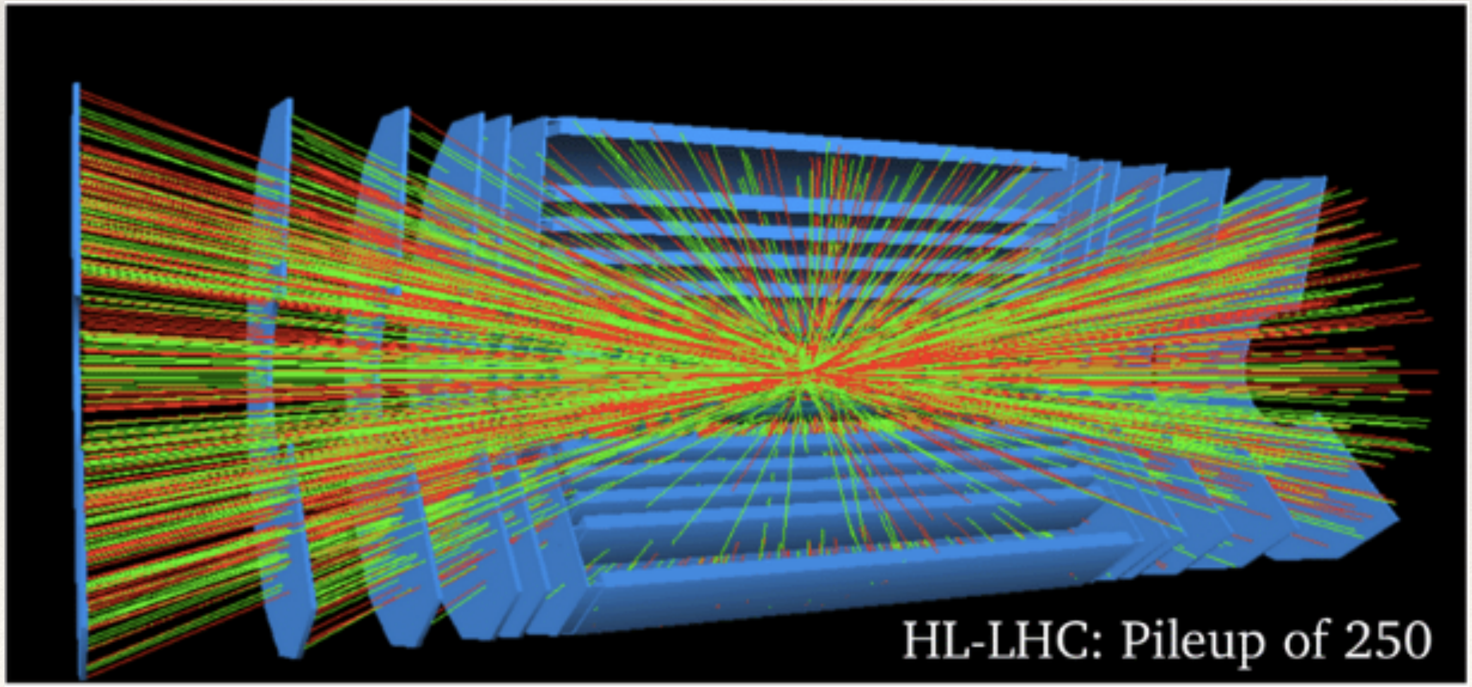
And this example refers actually to just ONE (and relatively simple) event..

- next..



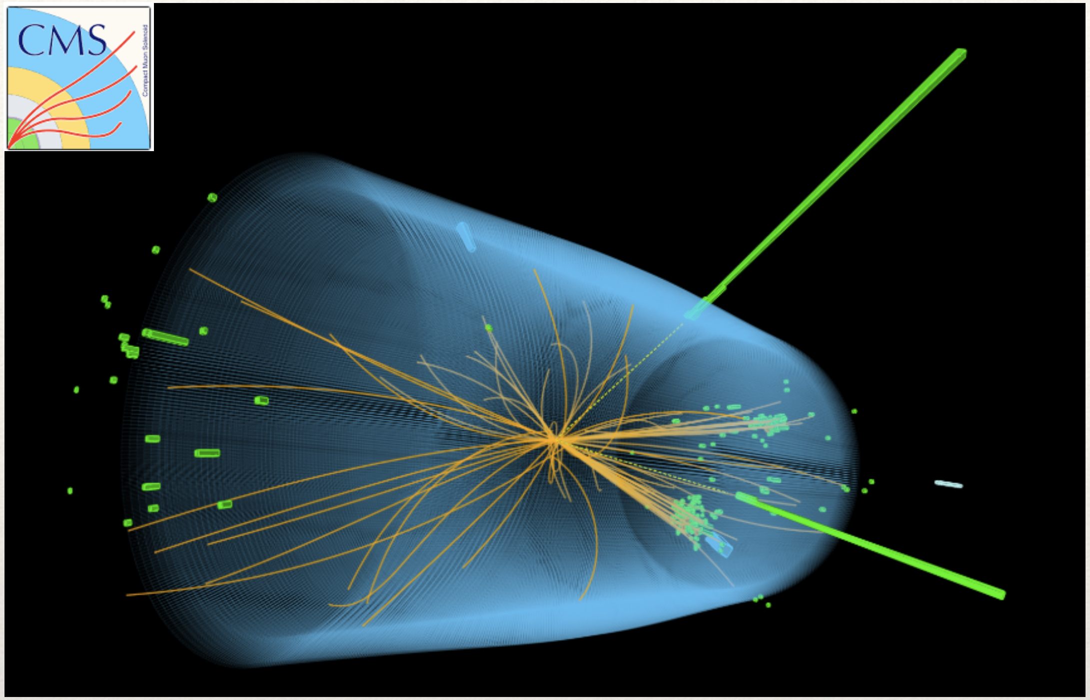


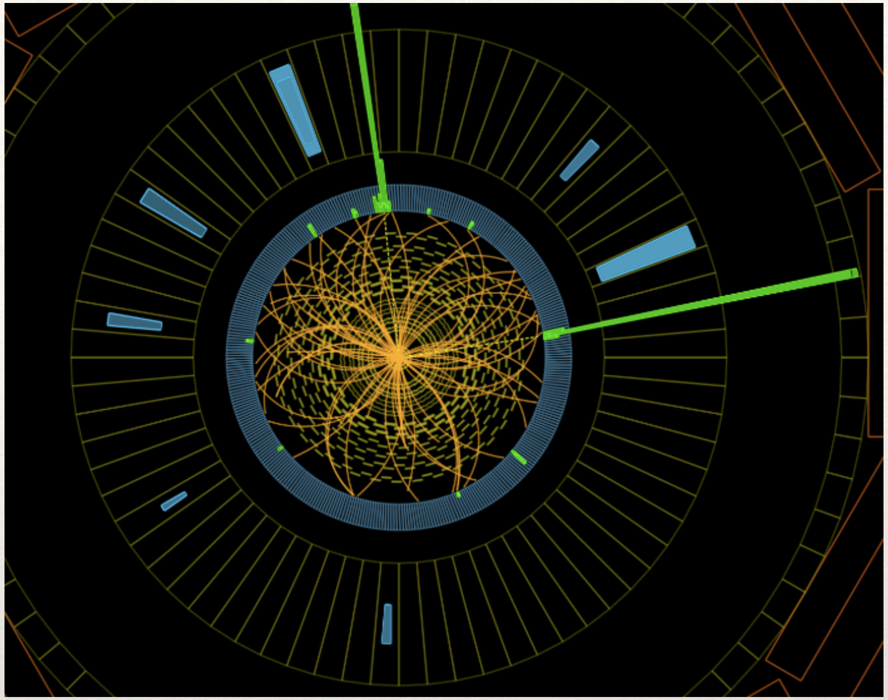
LHC: Pileup of 25



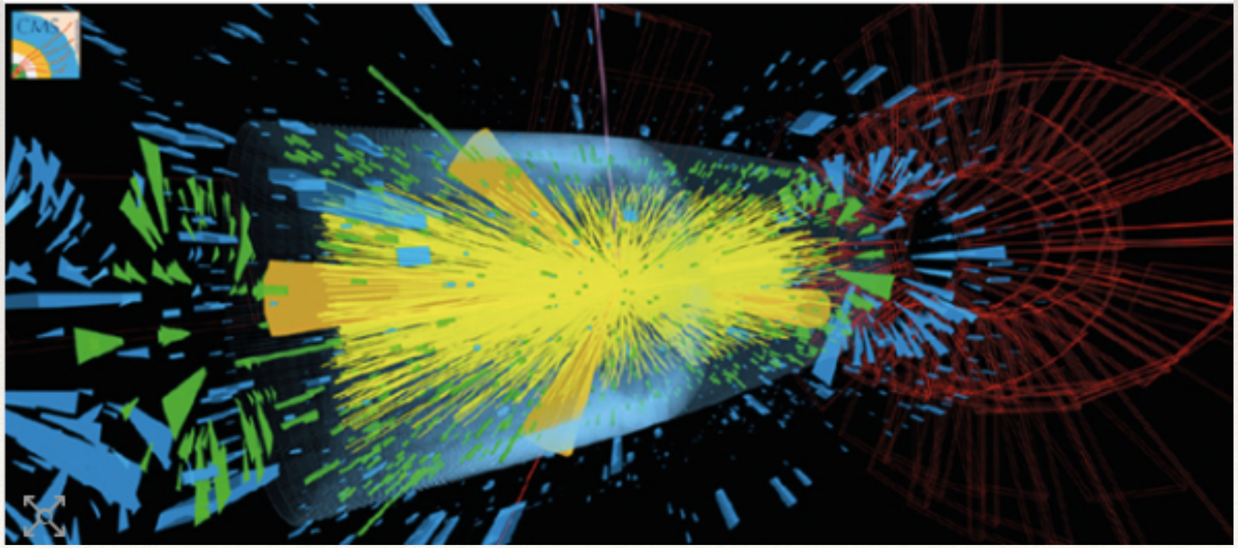
HL-LHC: Pileup of 250

Real event displays (e.g. CMS)





Top: H in $\gamma\gamma$, around 20 PU



Right: H in VBF, 200 PU

Computing resource optimisations

Industrial-scale data samples collected by e.g. LHC experiments produce non-collisions metadata from which actionable insights can be extracted

- results of logging while running Run-1/2 operations of complex Workload Management and Data Management systems

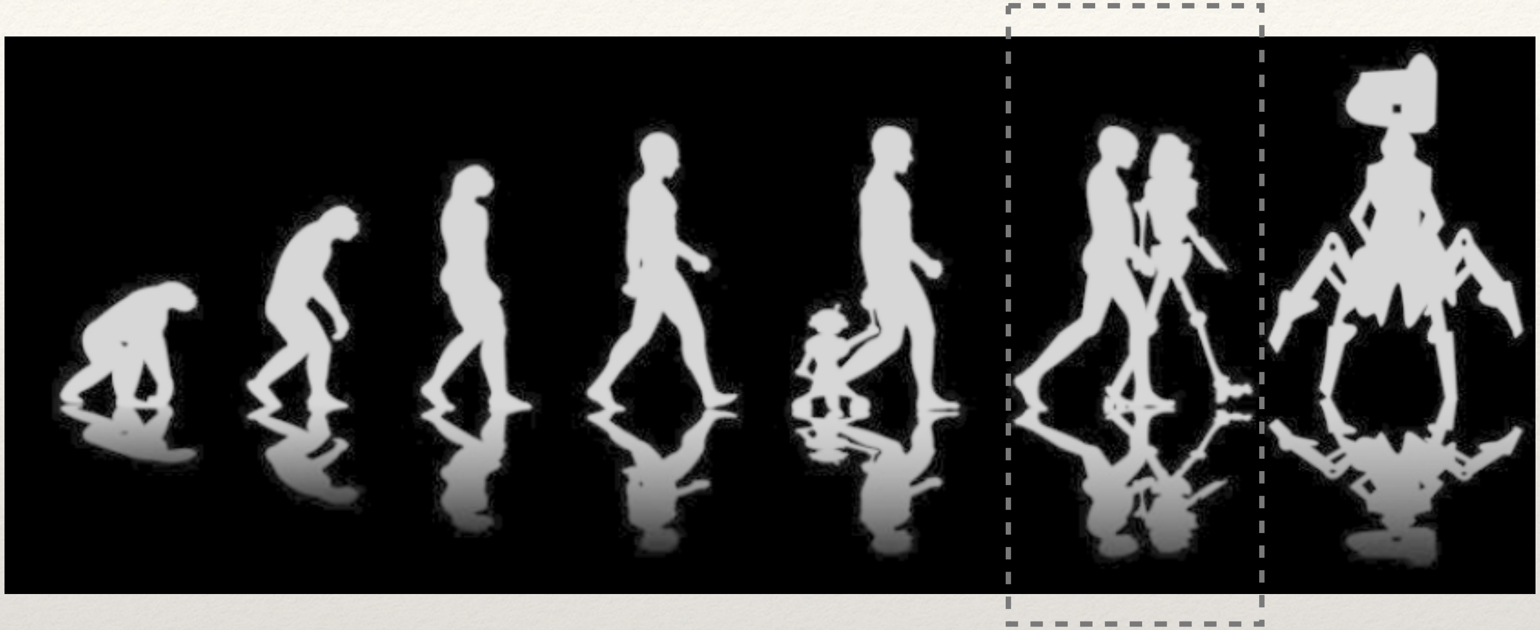
ML techniques have begun to play a crucial role in increasing the efficiency of computing resource usage for LHC experiments since few years

- e.g. predicting which data will be accessed the most to a-priori optimise data storage at Grid computing centres via pre-placement, or perform WAN path optimisation based on user access historical patterns (done/in-progress primarily, but not only, in **LHCb** and **CMS**)
- e.g. monitoring data transfer latencies over complex network topologies, using ML to identify problematic nodes and predict likely congestions (mostly by **CMS**)

Current approach is that ML outcome should inform the choices of the computing operations teams

- this might be the basis of fully adaptive models in the next future

Now to ~2020/22?



ML in HEP as **the use of full high-dimensional feature space to train cutting-edge ML algorithms (e.g. DNNs)**

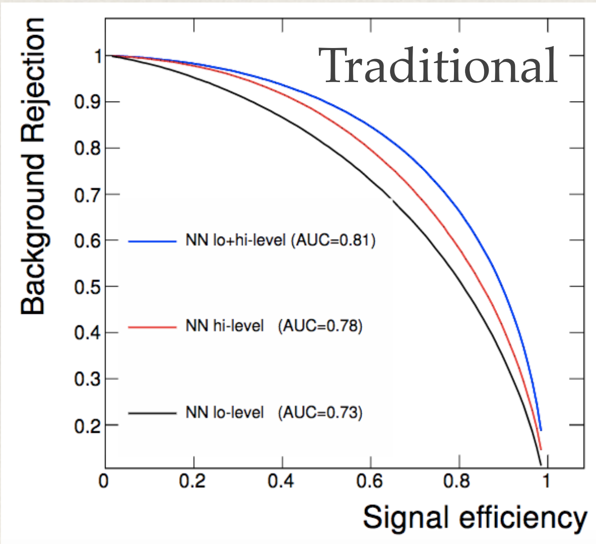
As in computer vision and NLP, growing effort in HEP too to skip the feature-engineering step. How well can we do using deeper networks and/or special architectures?

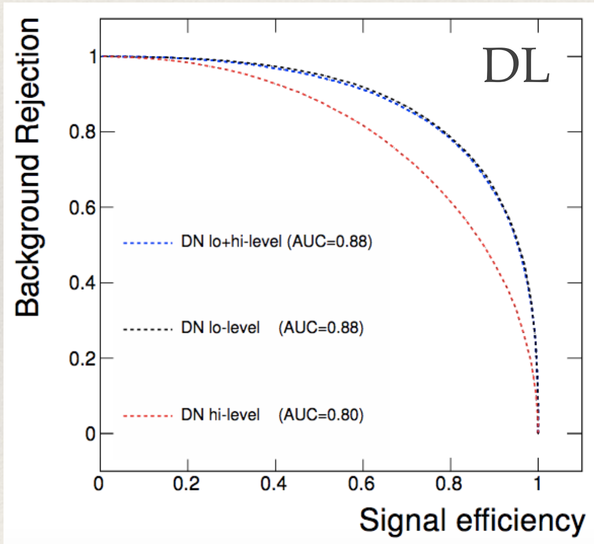
Do DNNs need us?

Does a DNN need high-level features like invariant masses, or can it just learn the physics by itself from the 4-vectors (once it is given examples)?

- If a DNN using low-level features outperforms any selection based only on high-level features..

ML models with limited capacity to learn complex non-linear functions of the inputs rely on painful manual construction of helpful non-linear feature combinations to guide the shallow networks. But recent DL advancements allow to automatically discover powerful non-linear feature combinations, thus providing better discrimination power.





Higgs benchmark: comparison of bkg rejection vs signal efficiency for the traditional learning method (left) and the DL method (right) using the low-level features, the high-level features and the complete set of features.

[arXiv:1402.4735]

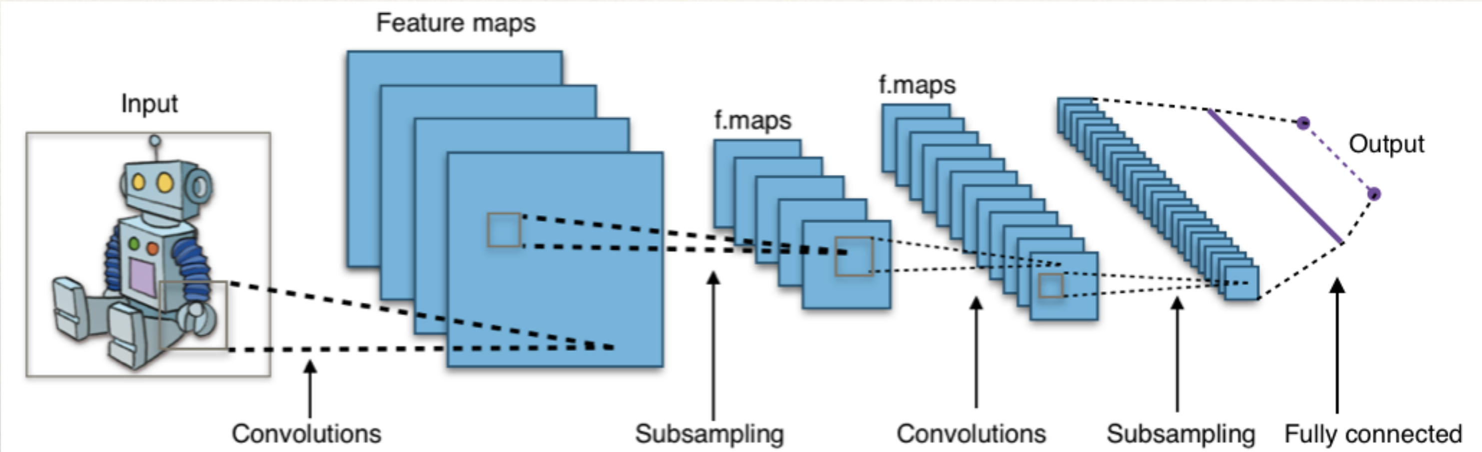
Demonstrated improvements O(~10%) over the best current approaches

- DL techniques can provide powerful boosts to searches for exotic particle

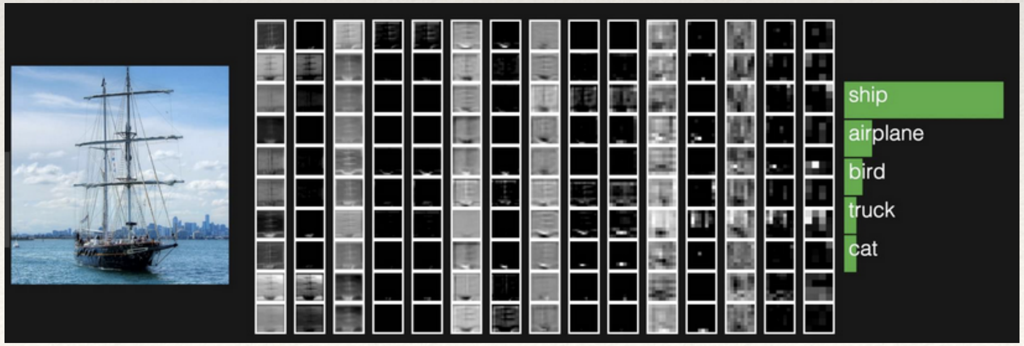
CNNs

CNNs are deep FFNNs with architecture inspired by the visual cortex

- CNN neurons seek local examples of translationally invariant features. Convolutional filters locate patterns producing maps of simple features. Complex features are built using many layers of simple feature maps.



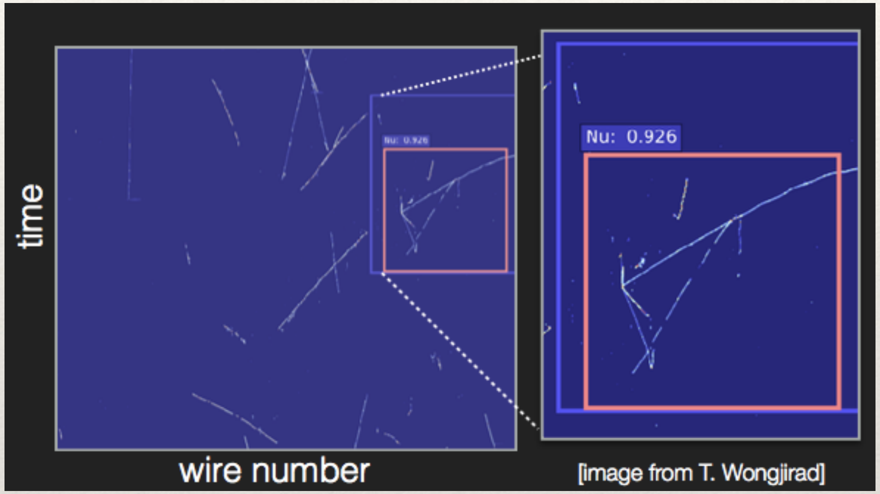
Used to solve a large variety of problems, including many in image recognition



CNNs for neutrinos

MicroBooNE has managed to train **CNN**s that can locate neutrino interactions within an event in the LArTPC, identify objects and assign pixels to them

- CNN perfect to identify objects in an image (translational invariant feature learning), and sensitive volumes are large due characteristics of neutrino interaction with matter

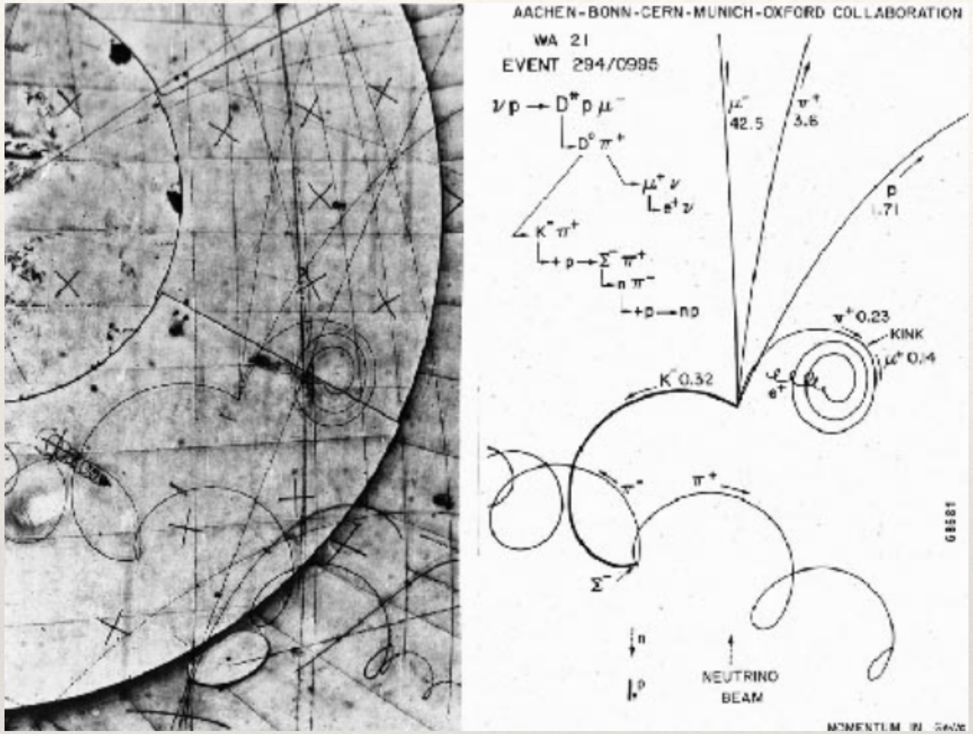


[more at arXiv:1611.05531]

Similar work ongoing at:

- other neutrino experiments - e.g. **NOvA** *[arXiV:1604.01444]*
  - inspired to GoogLeNet architecture. Improvement in the efficiency of selecting electron neutrinos by 40% with no loss in purity. Used as event classifier in both an electron neutrino appearance search, and in a search for sterile neutrinos
- collider experiments in the area of jet physics *[arXiv:1511.05190]* *[arXiv:1603.09349]*

Does this remind you of something?



Neutral currents in BEBC - WA21 CC Charm Event: Roll 204, Frame 995 [CERN]

The data taking pace has changed

- e.g. BEBC in 1973-83 equals to 6 seconds of (e.g.) LHCb today
- e.g. LHC sensor arrays' 1 hr equals to ~ Facebook data in 1 year
- algorithms running on large computing farms took over long ago

Still dealing with inability for humans to visually inspect vast amounts of data

- Indeed, inability "<u>for humans</u>"..

Arguing "HEP is different"..

[arXiv:1611.05531]

More on particle ID and particle properties

In CALOs or TPCs the data can be represented as a 2D or 3D image (even 4D, including timing information): the problem can be cast as a computer vision task.

DL techniques in which DNNs are used to reconstruct images from pixel intensities are good candidate to identify particles and extract many parameters

- promising DL architectures for these tasks include (at least) **CNN**, **RNN**
- e.g. LArTPCs is the chosen detection technology for **DUNE** (the new flagship experiment in the neutrino programme). A proof of concept and comparison of various DL architectures is expected to be finalised by 2020
- e.g. **b-tagging in collider experiments**. Techniques also from NLP are expected to be finalised by 2020

Simulation

Physics-based full simulation modelling in HEP (with GEANT 4 as the state of the art) is very computationally demanding

- e.g. for LHC, the large samples to be generated for future experimental runs and the increase in luminosity will exacerbate the problem, prohibitive also for GEANT

This already sparked the development of approximate, Fast Simulation solutions to mitigate this computational complexity - especially relevant in calorimeter showers simulations

Promising alternatives for Fast Simulation may be built on recent progress in high fidelity fast generative models

- e.g. Generative Adversarial Networks (**GAN**s) and Variational AutoEncoders (**VAE**s)
- ability to sample high dimensional feature distributions by learning from existing data samples

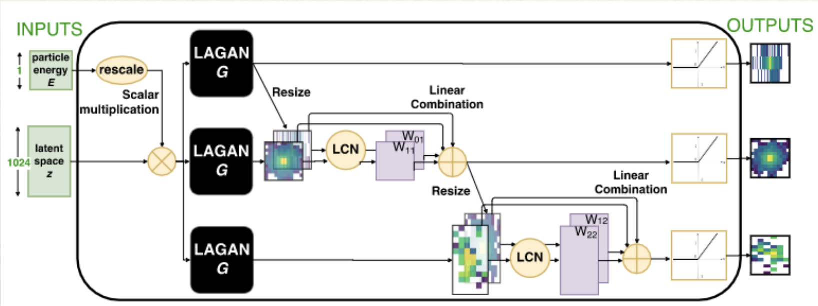
A simplified first attempt at using such techniques in simulation saw orders of magnitude increase in speed over existing Fast Simulation techniques, of which **all HEP experiments** would largely benefit

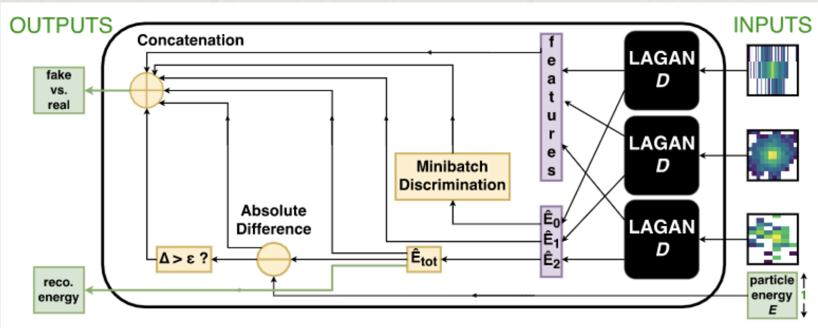
- not yet reached the required accuracy, though

Perhaps more towards >2020, but promising.

Simulation (cont'd)

E.g. exploit **GAN**s, a 2-NN game where one maps noise to images, and the other classifies the images as real vs fake (the best generator is the one that maximally confuses its adversary)





CaloGAN composite generator (up) and discriminator (down)

[arXiv:1712.10321]

E.g. **CaloGAN**, a new FastSimulation technique, to simulate 3D HEP showers in multi-layer ECAL systems with GANs

- basically, CaloGAN can generate the reconstructed Calo image using random noise, <u>skipping the GEANT and RECO steps - thus making it 10k faster than GEANT</u>..

HEP data format for ML

(might look ML-unrelated, but it deeply is)

HEP relies on the ROOT format for its data, whereas the ML worldwide community has developed several other formats (often associated with specific ML tools)

A desirable data format for offline usage with ML world-class applications and frameworks should have the following attributes:

- high read-write speed for efficient training
- sparse readability without loading the entire dataset into RAM
- high compressibility
- widespread adoption by the ML community

The thorough evaluation of the different data formats and their impact on ML performance for **all HEP experiments** is in progress.

- Strategy for bridging/migrating HEP formats to chosen ML format(s), or vice-versa, are being envisioned.

ML as-a-Service (MLaaS)

ML in production at scale is not only matter of software algorithms. Actually, it is mostly matter of <u>infrastructure</u>.

MLaaS emerging also in HEP as a possible range of services that offer ML tools as part of cloud computing services

- no need to install software or provision owned servers: the provider's data centres handle the actual computation

Not at all widely used in HEP, but first interesting attempts by pioneering experiments are appearing

- e.g. **CMS** has a working prototype of **TensorFlow-as-a-service (TFaaS)**, demonstrated for S/B discrimination in full hadronic top analyses, for event classification, etc. now evolved in a larger scope project (i.e. not only TF, and more..)

Range of potential benefits:

- incremental training + a plethora of trained models loadable and servable upon request
- optimal for prototyping, use of checkpoints, etc
- *an explorable "work model" for HEP: outsource the CS (ML) part of the work in a physics analysis team to a skilled sub-set of members + cloud resources*

Detector anomaly detection

WARNING: just one example of unsupervised..

Data taking continuously monitored by physicists taking shifts to monitor and assess the quality of the incoming data

- largely using reference histograms produced by experts

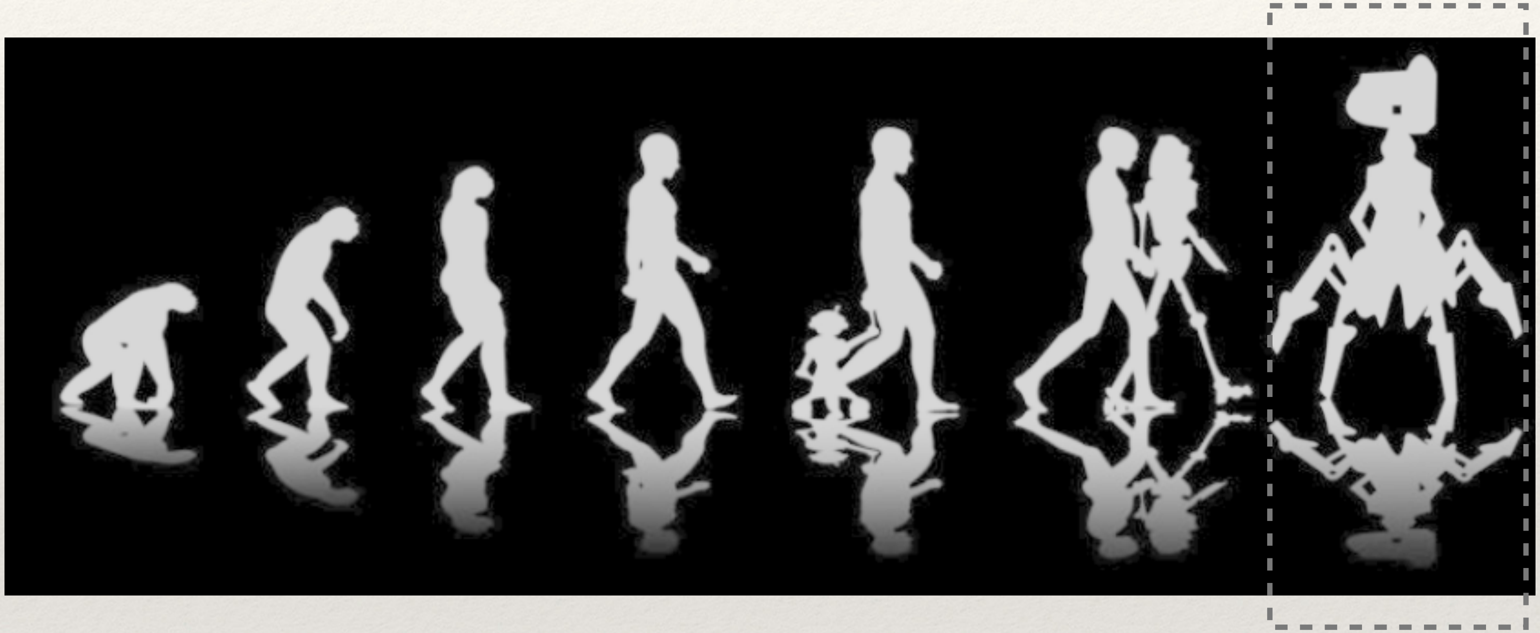
Automation may come from the whole class of "**anomaly detection**" ML algorithms

- **unsupervised algorithms** able to monitoring many variables at the same time, learn from data and produce an alert when deviations are observed
- synergy with **predictive maintenance** in industry: algorithms sensitive to subtle signs forewarning of imminent failure, so that pre-emptive actions can be scheduled

Work in progress by **various LHC experiments**

- and predictive maintenance of interest for LHC data centers, too

?



HEP A(G)I?

Aka “*send RAW data straight to some HEP AI and forget*”?

- meaning, is that an AGI, actually?!

Agnostically, check the requirements we need to maintain:

- ability to reformulate the problem (we do not know questions a-priori)
- modularity, i.e. also reusability
- interpretability / explainability
- easy validation
- ..

IMO: a omni-comprehensive “HEP AGI” is improbable any time soon (or even in general). But few modular “intelligent” adaptive systems based on advanced ML/DL able to make good use of Big Data and focus on some cross-experiment HEP tasks is not unthinkable.

One open (key) aspect are e.g. the systematic uncertainties..

Systematic uncertainties

We often do not know a-priori sizes and sources of systematic uncertainty…

- How can a ML algorithm be robust against systematic effects in the training samples, if we do not know how to transfer to it a knowledge we do not have?

Several approaches developed within HEP so far:

- define a physics-specific loss function that explicitly drives the ML optimisation to a solution that is invariant under changes in some (possibly completely unknown) features ***[arXiV:1305.7248] [arXiV:1410.4140]***
- enforce invariance using the adversarial network approach, where the adversary now tries to guess the value of the latent parameter ***[arXiV:1611.01046]***
- parametrise latent parameters such that the NN learns to smoothly interpolate itself as a function of the latent parameters ***[arXiV:1601.07913]***

Summary

The **use of ML** is becoming **extremely present in HEP at large**

- a rapidly evolving approach in HEP to characterising and describing data with the potential to radically change how data is reduced and analysed

Applications domain varies:

- Some will qualitatively (directly) improve the *physics reach of datasets.* Others will allow more efficient use of computing resources, thus (indirectly) extending the *physics reach of experiments*

DL is starting to make a visible impact in HEP

- firstly, with HEP problems that are closely related to those commonly solved using DL

Collaboration with **CS** and synergy with the **world-class ML community** is vital for HEP, and a challenge in itself for both sides!

- HEP has interesting features from a CS perspective (sparse data, irregular detector geometries, heterogeneous information, systematics, ..)
- HEP should be open to other communities, and improve in how to formulate problems in a way CS can understand and be attracted to

Plenty of cutting-edge **very** interesting work and R&D that I did not cover…

- (not exhaustive list!) hardware-side of choices, deployed computing infrastructures for ML in HEP, tracking challenges, jet tagging with RNNs, deep NNs on FPGAs, Deep Kalman Filters, compression using autoencoders, sustainable MEM, and more…

Machine learning at the energy and intensity frontiers of particle physics

Alexander Radovic[1]*, Mike Williams[2]*, David Rousseau[3], Michael Kagan[4], Daniele Bonacorsi[5,6], Alexander Himmel[7], Adam Aurisano[8], Kazuhiro Terao[4] & Taritree Wongjirad[9]

Our knowledge of the fundamental particles of nature and their interactions is summarized by the standard model of particle physics. Advancing our understanding in this field has required experiments that operate at ever higher energies and intensities, which produce extremely large and information-rich data samples. The use of machine-learning techniques is revolutionizing how we interpret these data samples, greatly increasing the discovery potential of present and future experiments. Here we summarize the challenges and opportunities that come with the use of machine learning at the frontiers of particle physics.

The standard model of particle physics is supported by an abundance of experimental evidence, yet we know that it cannot be a complete theory of nature because, for example, it cannot incorporate gravity or explain dark matter. Furthermore, many properties of known particles, including neutrinos and the Higgs boson, have not yet been determined experimentally, and the way in which the emergent properties of complex systems of fundamental particles arise from the

Big data at the LHC

The sensor arrays of the LHC experiments produce data at a rate of about one petabyte per second. Even after drastic data reduction by the custom-built electronics used to readout the sensor arrays, which involves zero suppression of the sparse data streams and the use of various custom compression algorithms, the data rates are still too large to store the data indefinitely—as much as 50 terabytes per second,

Review work published on **Nature** (Aug 2018)
