A novel dynamical mechanism of elementary particle mass generation has recently been conjectured and numerically demonstrated by lattice simulations (Phys .Rev. Lett. 123 061802 (2019)) in a simple SU(3) gauge model where a SU(2) doublet of strongly interacting fermions is coupled to a complex scalar field doublet through a Yukawa and a Wilson-like term. As a first step towards building a natural ('a la 't-Hooft) extension of the Standard Model, we argue that in the presence of weak gauge interactions the mechanism above, acting as a kind of non-perturbative anomaly, yields for both elementary fermions and weak gauge bosons effective masses proportional to the Λ -parameter of the theory, with particle-specific gauge coupling dependent prefactors. The low energy effective description of models based on such a mechanism is discussed, with focus on the predictive power about the scale of New Physics (Λ -parameter in the few TeV range) and its relation to the electroweak scale (and the Higgs boson mass).

I will report on the status of the analysis of the ensembles $N_f = 2 + 1 + 1$ isoQCD Wilson clover twisted mass focusing on scale setting, quark masses, meson decay constants.
