65th ICFA Advanced Beam Dynamics Workshop on High Luminosity Circular e⁺e⁻ Colliders (eeFACT2022)

Beam background status of Belle II at SuperKEKB

Andrii NATOCHII

On behalf of the beam background and MDI groups

University of Hawai'i at Mānoa <u>natochii@hawaii.edu</u>

INFN Frascati 2022

Outline

- Introduction
- Belle II and SuperKEKB
- Luminosity gain and consequences
- Beam background overview
 - Sources and mitigation
 - Measurements
 - Current status
 - Simulation
- Future plans and prospects
- Summary

- Goals of Belle and Belle II experiments
 - Study the *CP*-symmetry violation in the *B*-meson system
 - Searching for New Physics beyond the Standard Model
- Requirements for KEKB and SuperKEKB colliders
 - Produce a large number of *BB*-pairs
 - High collision luminosity
 - *B*-meson decay time difference (Δt) measurements
 - Asymmetric collider
 - Precise measurements of the *BB*-mixing rate
 - High quality spectrometer

Belle II and SuperKEKB

 $ab \equiv attobarn = 10^{-42} \text{ cm}^2$

KEKB/Belle

- Collected ~1 ab^{-1} of data ~10⁹ of $B\overline{B}$ -pairs
- Along with PEP-II/BaBar, observed large time-dependent *CP*-asymmetries

Contributed to the 2008 Physics Nobel Prize

SuperKEKB/Belle II

- Almost all subsystems are upgraded for better performances
- Nano-beam and Crab waist collision scheme
- Aims to collect **50 ab⁻¹** of data by the 2030s

Luminosity gain and consequences

- The SuperKEKB **design** has x40 higher luminosity ($L \sim I_{\pm} \beta_{y}^{*}$ [cm⁻²s⁻¹]) than KEKB with x2 higher beam currents (I_{\pm} [A]) and x20 smaller vertical beta functions (β_{y}^{*} [m]) at the interaction point (IP).
- This implies higher beam-induced backgrounds in the Belle II detector
 - High rate of particles leaving the beam
 - Requires a more frequent top-up beam injection
 - Sensitive detector and collider component damage
 - Reduces components longevity
 - High rate of beam losses in the interaction region
 - Increased Belle II hit occupancy and physics analysis backgrounds

Background sources

6

Background countermeasures

Particle scattering

Collimators (off-trajectory particles stop), Vacuum scrubbing (residual gas pressure reduction), Heavy-metal shield outside the IR beam pipe (detector protection against EM showers)

Synchrotron radiation

Beryllium beam pipe is coated with a gold layer + ridge surface of the beam-pipe + variable incoming beam pipe radius (to avoid direct SR hits at the detector)

Andrii Natochii

University of Hawaii

One of the most vulnerable sub-detectors is the Time of Propagation (TOP) particle ID system

- Current background rates in Belle II at ~1.2 A are acceptable and below limits
- Belle II did not limit beam currents in 2021 and 2022
 - It will limit SuperKEKB eventually, without further background mitigation
- To reach the **target** luminosity of 6.3x10³⁵ cm⁻²s⁻¹ an upgrade of crucial detector components is foreseen
 - (e.g. TOP short lifetime conventional PMTs)

Snowmass Whitepaper arXiv:2203.11349

Uncontrolled beam losses

- During stable machine operation unexplained beam instabilities and beam losses may occasionally occur in one of the rings causing sudden beam losses (SBLs) at a specific location around the ring due to
 - Machine element failure
 - Beam-dust interaction
 - Vacuum element defects
- Consequences
 - Detector and/or collimators damage, see Figure
 - Belle II background increase
 - Superconducting magnet quenches
- Usually only a few such catastrophic beam loss events happen per year in each ring
 - In 2022, we had many (>50) SBLs in the LER trying to go beyond 0.7 mA/bunch
- Cures
 - $\circ \quad \text{Upgraded abort system} \rightarrow \text{fast abort signal}$
 - \circ Low-Z materials for collimator heads (MoGr, Ta+Gr) \rightarrow robust collimators
 - Understand the source of the unstable beam (vacuum system inspection, beam dynamics study, installation of additional beam loss monitors around the rings)

Background simulation: Tools

- **Single-beam background** (Beam-gas & Touschek)
 - Strategic Accelerator Design (SAD@KEK) (multi-turn particle tracking)
 - Realistic collimator profile and chamber
 - Particle interaction with collimator materials
 - Measured residual gas pressure distribution around each ring
 - Geant4 (detector modelling)
- Luminosity background:
 - Geant4 (single-turn effect, colliding bear
- Synchrotron radiation background:
 - Geant4 (close to the Belle II detector)

Collimator chamber 3D model (a) and simulated absorbed particles at a collimator (b)

Measured and estimated vacuum pressure distribution around the LER

Background simulation: Accuracy

Ratios of measured (data) to simulated (MC) backgrounds based on dedicated studies in 2020-2021

- Current data/MC ratios are within one order of magnitude from unity
 - Substantial improvement compared to measurements in 2016 [link] and 2018 [link]
 - It confirms our good understanding of beam loss processes in SuperKEKB
- These ratios are used to rescale simulated backgrounds toward higher luminosities

Our simulation with a good data/MC agreement helps us to

- Study an impact of beam optics parameters on Belle II backgrounds
- Develop new collimators
- Better mitigate backgrounds through machine or detector adjustments and upgrades
- Predict background evolution at future machine settings
 - Backgrounds will remain high but acceptable until the luminosity of about 2.8x10³⁵ cm⁻²s⁻¹
 - For the target luminosity of about 6.3x10³⁵ cm⁻²s⁻¹
 machine condition is very uncertain to make an accurate background prediction

Measured and predicted Belle II backgrounds

Future plans and prospects

To reach the **target** luminosity of 6.3×10^{35} cm⁻²s⁻¹ by 2030s we plan

- Detector upgrades (e.g. PXD, TOP PMTs) [LS1]
 - Damage sensors replacement
 - Fully assembled PXD with two layers
 - Replaced short-lifetime conventional PMTs in the TOP
- Additional shielding in/outside Belle II against SR, EM-showers and neutrons [LS1]
 - More polyethylene and concrete shieldings on endcaps and around the final focusing magnets
 - New IP beam pipe
- Collimation system upgrade [LS1, LS2]
 - Nonlinear collimation (NLC) insertion in the LER
 - Low impedance budget
 - Better background control
 - More robust collimator heads installation (MoGr, Ti, Ta+Gr)
- IR redesign [LS2]
 - To use the crab waist scheme at $\beta_v^* = 0.3$ mm
- Injection chain and feedback system upgrade [LS1, LS2]
 - For stable machine operation at low injection backgrounds

LS stands for the Long Shutdown, which is the period of no beam used for machine and detector upgrades

Summary

- In 2022, SuperKEKB and Belle II reached the world record luminosity of ~4.7x10³⁴ cm⁻²s⁻¹
 - This success required a close collaboration between machine and detector experts to keep the balance between high collision rate and acceptable background level in Belle II avoiding unwanted detector and machine damages
- We have successfully reached a good agreement between measured and simulated beam-induced backgrounds which helps us to study future background evolutions [<u>link</u>]
- In the next decade, at stable machine operation, backgrounds in Belle II are expected to remain acceptable until at least the luminosity of 2.8x10³⁵ cm⁻²s⁻¹ [*link*]
- Further machine and detector improvements are foreseen
- We are closely collaborating with other accelerator laboratories around the globe on optimizing upgrades of SuperKEKB and reaching the target luminosity of about 6.3x10³⁵ cm⁻²s⁻¹

The Belle II beam background and MDI groups are open to new people motivated and willing to bring their fresh ideas and unique expertise in beam background mitigation for safe and productive machine and detector operation

Beam BG status of Belle II at SuperKEKB

Luminosity degradation & crab waist scheme

• Initially

- Was hard to operate the SuperKEKB near the working point of the betatron tune (.57,.61)
 - \leftarrow due to luminosity degradation caused by beam-beam resonances
- Since early 2020
 - Used a set of dedicated sextupoles for the crab waist scheme
 - ← does not affect the dynamic aperture
 - ← beam-beam resonances are suppressed

Crab Waist collision scheme: a) crab sextupoles OFF; b) crab sextupoles ON

Belle and KEKB (1999-2010)

HER High Energy Ring

LER Low Energy Ring

CM-energy is at Y(4S)resonance = 10.58 GeV for efficient $B\overline{B}$ -pair production

- Designed and optimized for the observation of *CP*-violation in the *B*-meson system.
- Collected > 1 ab⁻¹ of data for Y(1S), Y(2S), Y (4S) and Y(5S) resonances

Timeline for machine upgrade

 \rightarrow

- Phase 1 (2016)
- Phase 2 (2018)
- Phase 3 (2019)

- \rightarrow Accelerator commissioning
 - First collisions; partial detector; background study; physics possible
- \rightarrow Nominal Belle II start

Background measurements

A dedicated beam-induced background measurement is performed to measure each background component separately, usually twice a year

An example of dedicated beam background measurements in SuperKEKB. Top: typical measured detector background; bottom: measured machine parameters.

Andrii Natochii

[P.M.Lewis *et al.*, "First measurements of beam backgrounds at SuperKEKB", <u>NIMA</u> 2019]

Combined results. In order to determine the overall level of agreement between experiment and simulation, we combine results from all detectors and channels. The systematic uncertainties of Fig. 67 are incomplete and cannot be used to weight channels in a global average. Furthermore, the variation of the points is much larger than the single-channel uncertainty. Consequently we discard the uncertainties and calculate the unweighted mean of the common logarithm of the channel ratios. The uncertainty then is the standard error on the mean. Finally, we convert the logarithms back to simple ratios and obtain our combined ratios with asymmetric errors.

We obtain the following combined experiment/simulation ratios:

- LER beam-gas: $2.8^{+3.4}_{-2.3}$,
- LER Touschek: $1.4^{+1.8}_{-1.1}$,
- HER beam-gas: 108_{-64}^{+180} ,
- HER Touschek: $4.8^{+8.2}_{-2.8}$.

Figure 19: (color online) Ratio of observed to predicted Touschek background rates in all detectors studied with old (top) and new (bottom) simulation. Blue (Red) points represent HER (LER) results. From top to bottom, the detectors are ordered from radially outermost (TOP) to inermost (PXD). Figure 20: (color online) Ratio of observed to predicted Touschek background rates in all detectors studied with old (top) and new (bottom) simulation. Blue (Red) points represent HER (LER) results. From top to bottom, the detectors are ordered from radially outermost (TOP) to inermost (PXD). Data-to-simulation Monte Carlo (Data/MC) fit results for all BEAST II and Belle II detectors are summarized in Figure 19 for Touschek backgrounds and Figure 20 for beam-gas results. Values for individual detector channels or physical locations, where applicable, are shown as separate points. The top plot in each figure represents the results of the Data/MC fits using the "old" simulation, while bottom plots show the same results using MC updated to better model the detector. Data/MC fit results are improved markedly with the new simulation, usually by orders of magnitude. Table 2 combines the individual detector results into a single overall ratio for Touschek and beam-gas backgrounds in the LER and HER. In Section 7 we use these

Ring	Background Source	October 2018 Simulation	February 2019 Simulation	October 2018/February 2019 Ratio
LIED	Touschek	127.82	113.91	1.12
HEK	Beam-gas	483.50	32.28	14.98
IED	Touschek	1.62	0.63	2.57
LEK	Beam-gas	29.39	2.79	10.53

Table 2: Comparison of combined detector data/MC ratios, excluding PLUME. Averages are calculated first by taking the mean of all channels in each BEAST or Belle II detector, and then combining them into an average of averages.

Our simulation reproduces the measured background in the IR at different collimators apertures

- D06V1 is the narrowest vertical collimator in the LER
- D02H4 is the closest to the IP horizontal collimator
- Tip-scattered particles contribute to the IR background

There is a good agreement between measurements and simulation

Unexpected machine impedance

Expected beam losses due to the Transverse Mode Coupling Instability (TMCI)

- A result of the wake-field effect from bunches traveling through the ring aperture
- Leads to the onset of the bunch current head-tail instability
- Depends on the most narrow and steep aperture in the ring (collimators)
 - Beam size blow up, see Figure
 - Betatron tune shift

- In 2020-2021, beam instabilities were one of the sources limiting bunch current increase
 - > At higher bunch currents, may need to open collimators further and accept higher backgrounds
- When predicting future background levels, we take this expected effect of TMCI on collimator settings into account, but not all contributions are fully understood such as unexpected tapered IR beam pipes wake-fields and the bunch-by-bunch feedback system impact
- Therefore, dedicated measurements of beam instabilities and studies of their mitigation are ongoing.

Injection background: CDC performance degradation

- Reduction of the injection veto dead time
 - Fixed veto pattern \rightarrow Will study variable pattern (veto only when TRG hits exceed some limit)
- Reduction of the injection background and duration
 - Need more investigation and simulation to understand the injection background.
 - Will consider how to prevent the collimator head being damaged.
 - Need to pin down the cause of the fast beam loss.

K. Matsuoka (KEK) C. Niebuhr (DESY)

Injection background: CDC observable

B. Schwenker (Univ. of Göttingen) C. Niebuhr (DESY)

Nonlinear collimation (NLC)

Create a nonlinear optics region by using a pair of skew-sextupoles in the Oho-section + V-collimator

- Low betatron function in between $\beta_{x/y} \sim 3m$
- Vertical angular kick for distant halo particles in both planes $\Delta p_v \sim (y^2 x^2)$
- A big aperture step ~1mm affects < 4σ at the QC1 \rightarrow fine tuning with the NLC
 - For other V-collimators: ~1mm step \Rightarrow 20-40 σ at the QC1

Introduced by K.Oide, KEK, 2021

- Consider a collimation at a vertical amplitude $y_{\rm q}$, which is equal to the dynamic aperture.
 - For the (60,0.6) mm optics, $y_{\rm q}=10.0\,{\rm mm}$ at QC1 (30 σ_y with $\varepsilon_y/\varepsilon_x=2\%).$
- It is equivalent to $y_{\rm s}=y_{\rm q}\sqrt{\beta_{y{\rm s}}/\beta_{y{\rm q}}}=6.8\,{\rm mm}$ at the NLC skew sextupole SNLC.
- The sextupole kicks the beam vertically by

$$dp_{ys} = \frac{s'}{2} (y_s^2 - x_s^2) \,, \tag{1}$$

$$' \equiv \frac{L_{\rm s}}{B\rho} \frac{\partial^2 B_x}{\partial y^2} \,. \tag{2}$$

- For instance, $s' = 6.0/\text{m}^2$, $\Delta p_{ys} = 0.14 \text{ mrad}$, with $|y_s| \gg |x_s|$.

• Then the kick makes a vertical displacement at the collimator:

$$\Delta y_{c} = R_{34} \Delta p_{ys} = 5.7 \text{ mm}$$
(3)
$$R_{34} \approx \sqrt{\beta_{wc} \beta_{ys}} = 40.8 \text{ m}$$
(4)

• This example optics: $\beta_{ys} = 570 \text{ m}, \beta_{yc} = 2.9 \text{ m}.$

Andrii Natochii

INFN Frascati 2022

30

NLC benefits

- Does not affect significantly the TMCI limit
 - May be tightly closed while other collimators may be opened
- Effectively suppresses Belle II backgrounds
 - Helps to control beam backgrounds leaving more margin for the injection background and other unexpected beam losses
- Collimates in both planes stopping stray particles due to beam-gas and Touschek scatterings
- Does not require high positioning accuracy
 - For $\beta_y^* = 0.6$ mm, ~1 σ of the aperture change at QC1 **D06V1**: 55 µm step

D02V1: 25 µm step

NLC: 250 µm step

- 1) Although the Belle II background is below the detector limit at $\beta_y^* = 0.6$ mm optics without NLC, there could be some unexpected beam losses and injection performance degradation leading to the background increase exceeding the detector limit. Since tightening of the key collimators reduces TMCI limit, NLC may help to suppress Belle II backgrounds keeping the bunch current limit unchanged.
- 2) NLC looks promising for a better beam background control at design optics of $\beta_y^* = 0.3$ mm. Even if we are limited to use only one V-collimator, NLC may be used in addition without affecting the TMCI limit and effectively suppressing backgrounds \rightarrow need more studies, $\beta_y^* = 0.3$ mm optics with NLC is not available for now.

Collimator damage and background history for 2022

Hypothesis for elevated backounds

- Throughout the run, backgrounds increase with beam currents (expected and unavoidable).
- As we increase beam-currents, the rates of catastrophic beam-loss events increase.
- This damages collimator jaws. Collimator team is then forced to re-adjust and typically open the collimators further.
- Both collimator jaw damage and opening collimators lead to an *additional* background increase as the run progresses.
- Collimator damage accumulates. Background situation gets progressively worse throughout the run.
- This also puts a lot of stress on the collimator group.

Time to consider collimator system upgrade?

- More robust collimator heads
- Faster + cheaper to replace
- More granular and stable jaw positioning
- Automatic / improved absolute alignment

Vahsen

Neutrons from the accelerator tunnel

- Neutron shielding around Belle II is not ideal and there is neutrons leakage
 - Detector performance degradation
- Monte-Carlo simulation predicts neutrons due to single-beam and collision (luminosity) beam losses.

- Above shows MC neutrons that pass through each TPC, traced back to their production point along the beam line from the 05-09-2020 FarBeamLine MC sample
- In both tunnels, the majority of luminosity background induced neutron production comes from localized regions (shaded green regions) -> call them RBB hotspots Based on J. Schueler slides, UH

Neutrons from collimator hotspots

- The highest beam losses are at the nearest collimators to the IR (D02H4 LER, D01H5 HER), ~16m from IP
- Move hotspots away from Belle II
 - Reduce losses at these collimators by closing far upstream collimators

Neutrons from luminosity hotspots

- Time Projection Chamber (TPC) measurements suggest localized regions along the beamline where neutrons originating from
 - Leading background in the forward cavern
 - Can be mitigated only via shielding, design is ongoing

Background simulation: Tools

- **Single-beam background** (Beam-gas & Touschek)
 - Strategic Accelerator Design (SAD@KEK) (multi-turn particle tracking)
 - Realistic collimator shape and chamber
 - Particle interaction with collimator materials
 - Measured residual gas pressure distribution around each ring
 - Geant4 (detector modelling)
- Luminosity background:
 - Geant4 (single-turn effect, colliding bear
- Synchrotron radiation background:
 - Geant4 (close to the Belle II detector)

Collimator chamber 3D model (a) and simulated absorbed particles at a collimator (b)

Measured and estimated vacuum pressure distribution around the LER

Background simulation: Detector response

- After particle tracking in SAD
 - Lost particles within the extended interaction region (±30m from the IP) are transferred to Geant4
- Geant4 simulation
 - Includes a realistic model of the detector and its surroundings (e.g. collider cavern)
 - Generates lost particles onto the inner surface of the beam pipe
 - Propagates primary and secondary (e.g. EM showers) particles through the detector
 - Produces output files with collected particle hit information mimicking detector response

Recently improved *Geant4* model of Belle II and collider cavern. Black dots represent single-beam losses
