Strange quark content of nucleon via reweighting on (2+1)-flavor Domain Wall Fermion lattices

Tuesday, 15 June 2010 14:50 (20 minutes)

The slope of nucleon mass with respect to the dynamical strange quark mass is directly related to the strange quark content of nucleon $(\langle N | \bar{s}s | N \rangle)$. This slope can be calcuated by shifting of dynamical strange quark mass via reweighting on dynamical ensembles, which allows a relatively inexpensive evaluation of the quantity without direct evaluation of disconnected diagrams. Calculation of $\langle N | \bar{s}s | N \rangle$ on $a^{-1} \sim 1.7$ and 2.3 Gev (2+1) flavor dynamical Domain Wall Fermion ensembles RBC/UKQCD collaborations generated are reported.
