Low energy charmonium-nucleon scattering with twisted boundary conditions

Friday, 18 June 2010 14:50 (20 minutes)

We study the charmonium-nucleon interations at low energies by extended L¥"ushcer formula with partially twisted boundary conditions, which allows us to calculate the s-wave phase shift at any small value of the relative momentum even in a finite volume. Our exploratory stude are carried out in quenched lattice QCD with non-perturbatively O(a)-improved Wilson fermions for light quarks and a relativistic heavy quark action for charm quark.

We have successfully evaluated both scattering lengths and effective ranges of eta_c-nucleon and J/psi-nucleon through this new approach. We also report on preliminary results calculated on 2+1 flavor PACS-CS configuration.
