Hadron Structure via Background Fields

Interaction energy of a hadron in the presence of external electromagnetic fields:

$$\begin{aligned} H = & -\vec{\mu} \cdot \vec{B} - \frac{1}{2} \alpha E^2 - \frac{1}{2} \beta B^2 \\ & - \frac{1}{2} \gamma_{E1} \sigma \cdot \vec{E} \times \dot{\vec{E}} - \frac{1}{2} \gamma_{M1} \sigma \cdot \vec{B} \times \dot{\vec{B}} \\ & + \gamma_{E2} \sigma_i E_{ij} B_j - \gamma_{M2} \sigma_i B_{ij} E_j \\ & - \frac{1}{12} \alpha_{E2} E_{ij}^2 - \frac{1}{12} \beta_{M2} B_{ij}^2 + \dots \end{aligned}$$

Time and spatial derivatives : $\dot{E} = \frac{\partial E}{\partial t}$, $E_{ij} = \frac{1}{2} (\nabla_i E_j + \nabla_j E_i)$, etc

Probe of internal structure of the system in increasingly finer detail.

μ , α , β :

static bulk response

others :

spatial and time resolution

Mass shifts: $\delta m(B) = m(B) - m(0) = c_1 B + c_2 B^2 + c_3 B^3 + c_4 B^4 + \dots$

Introduction of an external electromagnetic field on the lattice

- Minimal coupling in the QCD covariant derivative in Euclidean space

$$D_{\mu} \rightarrow \partial_{\mu} + gG_{\mu} + qA_{\mu}$$

- Recall that SU(3) gauge field is introduced by the link variables

$$U_{\mu}(\mathbf{x}) = \exp(iag G_{\mu})$$

- It suggests multiplying a U(1) phase factor to the links

$$U'_{\mu}(\mathbf{x}) = \exp(iaqA_{\mu})U_{\mu}$$

- This should be done in two places where the Dirac operator appears: both in the dynamical gauge generation and quark propagator generation

For Example

- To apply magnetic field **B** in the z-direction, one can choose the 4-vector potential

$$A_\mu \equiv (\phi, \vec{A}) = (0, 0, Bx, 0)$$

then the y-link is modified by a x-dependent phase factor

$$U_y \rightarrow \exp(iqaBx)U_y$$

$$\vec{B} = \nabla \times \vec{A}$$

$$\vec{E} = -\nabla\phi - \frac{\partial\vec{A}}{\partial t}$$

- To apply electric field **E** in the x-direction, one can choose the 4-vector potential

$$A_\mu = (0, Et, 0, 0)$$

then the x-link is modified by a t-dependent phase factor

$$U_x \rightarrow \exp(iqaEt)U_x$$

Computational Demands

$$U_y \rightarrow \exp(iqaBx)U_y$$

- Consider quark propagator generation

$$\frac{\int DG_\mu \det(\mathcal{D} + m_q) e^{-S_G} (\mathcal{D} + m_q)^{-1}}{\int DG_\mu \det(\mathcal{D} + m_q) e^{-S_G}}$$

$$D_\mu \rightarrow \partial_\mu + gG_\mu + qA_\mu$$

- **Fully dynamical:** For each value of external field, a new dynamical ensemble is needed that couples to u-quark ($q=1/3$), d- and s-quark ($q=-2/3$) in the sea. Valence quark propagator is then computed on the ensembles with matching values.
- **Re-weighting:** Perturbative expansion of action in terms of external field. Can use existing dynamical ensembles.
- **U(1) quenched:** no charging the sea, only coupling to the valence on:
 - Dynamical QCD ensembles
 - Quenched QCD ensembles

$$U_y \rightarrow \exp(iqaBx)U_y$$

What about boundary conditions?

- On a finite lattice with periodic boundary conditions, to get a constant magnetic field, B has to be quantized

$$qBa^2 = \frac{2\pi n}{N_x N_y}, \quad n = 1, 2, 3, \dots$$

to ensure that the magnetic flux through the plaquettes in the x-y plane is constant.

- But, for $N_x=N_y=24$ and $1/a=2$ GeV, the quantized field values are too strong for small-field expansion. So we have to abandon the quantization condition, and work with much smaller fields.
- To minimize the boundary effects, we work with **fixed b.c. in x-direction**, so that quarks originating in the middle of the lattice has little chance of propagating to the edge.

Magnetic moment in background field

- For a particle of spin s and mass m in small fields,

$$E_{\pm} = m \pm \mu B$$

where upper sign means spin-up and lower sign spin-down, and

$$\mu = g \frac{e}{2m} s$$

- g factor (magnetic moment in natural magnetons) is extracted from

$$g = m \frac{(E_+ - m) - (E_- - m)}{eBs}$$

Lattice details

$$U_y \rightarrow \exp[iqaB(x - x_0)]U_y$$

- **Standard Wilson gauge action**

- $24^3 \times 48$ lattice, $\beta=6.0$ (or $a \approx 0.1$ fm)
- 990 configurations

- **Standard Wilson fermion action**

- Set 1: Pion mass about 500, 646, 782, 894, 1010, 1434 MeV
- Set 2: Pion mass about 338, 362, 384, 405, 444, 693 MeV
- Boundary conditions: Dirichlet in x, y and t, periodic in z
- Quark source location $(t,x,y,z)=(0,12,12,12)$
- Polyakov loop origin $x_0=12$

- The following 5 dimensionless numbers $\eta \equiv qBa^2 = +0.00036, -0.00072, +0.00144, -0.00288, +0.00576$ correspond to 4 **small B fields**

$eBa^2 = -0.00108, 0.00216, -0.00432, 0.00864$ for both u and d (or s) quarks.

- Small in the sense that the mass shift is only a fraction of the proton mass: $\mu B/m \sim 1$ to 5% at the smallest pion mass. In physical units, $B \sim 10^{13}$ Tesla.

Baryon Two-point Correlation Function

$$\begin{aligned} G(t) &= \sum_{\vec{x}} \langle vac | T [\chi_1(x) \overline{\chi}_1(0)] | vac \rangle \\ &= (1 + \gamma_4) [A_+ e^{-m_+(t-t_0)} + bA_- e^{-m_-(N_t+t_0-t)}] \\ &\quad + (1 - \gamma_4) [bA_+ e^{-m_+(N_t+t_0-t)} + A_- e^{-m_-(t-t_0)}] \end{aligned}$$

b = 0 fixed (Dirichlet)

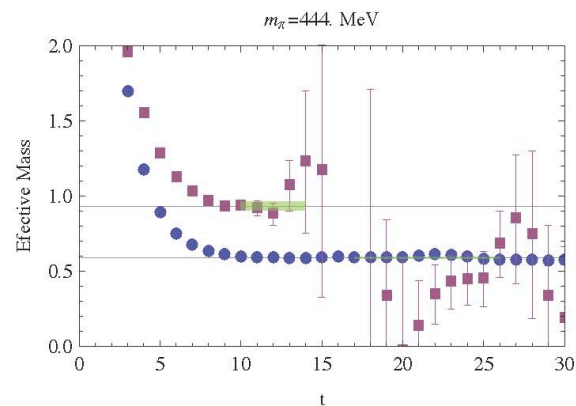

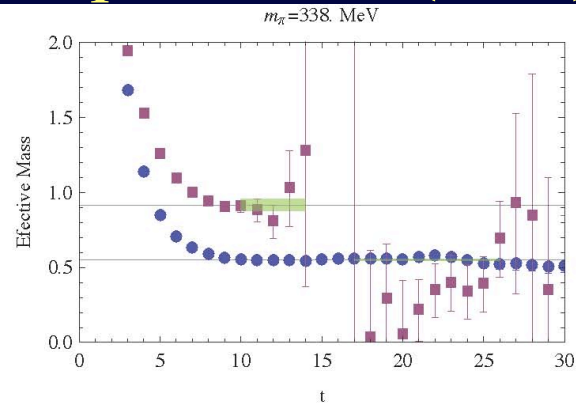

b = 1 periodic

b = -1 anto-periodic

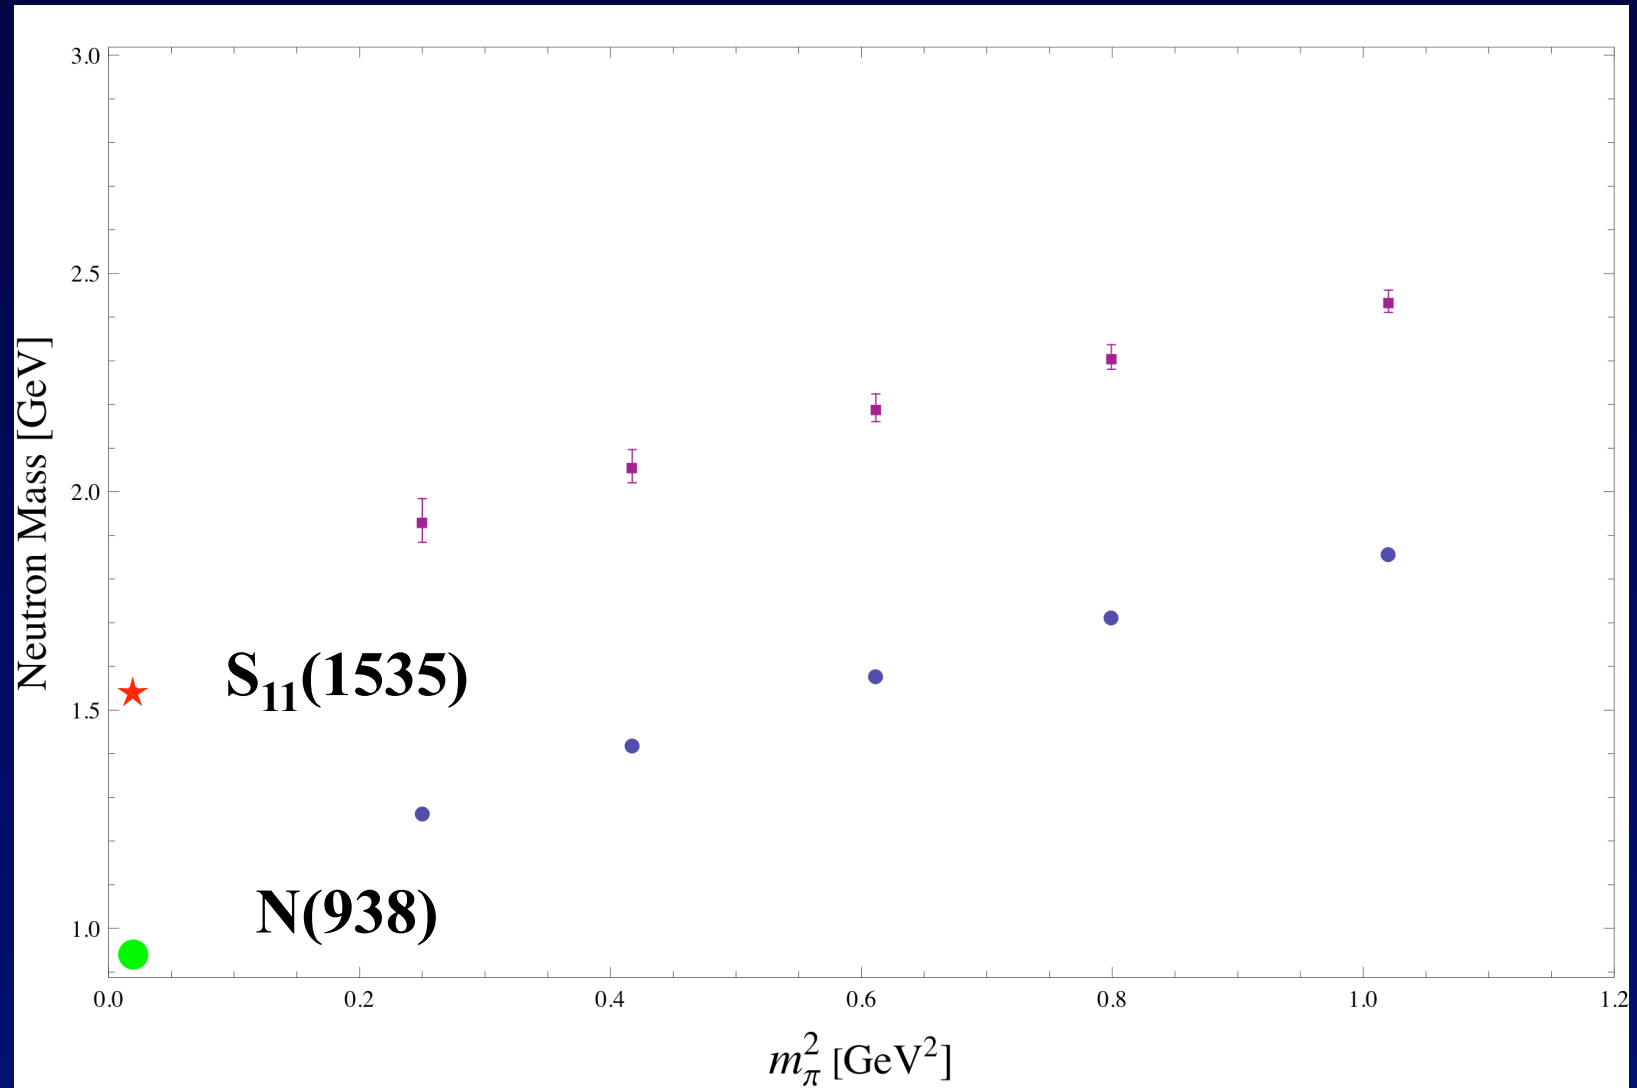

$$\chi_1 = \varepsilon_{abc} (u^{aT} C \gamma_5 d^b) u^c$$

Effective mass plots for $N(1/2^+)$ and $N^*(1/2^-)$ states

- Good signal for $N(1/2^+)$: fit 17-26
- Noisy signal for $N(1/2^-)$: fit 10-14

Masses for $N(1/2^+)$ and $N^*(1/2^-)$ states

Ratio of correlation functions for $p(1/2^+)$ and $p^*(1/2^-)$ (slope is related to g factor)

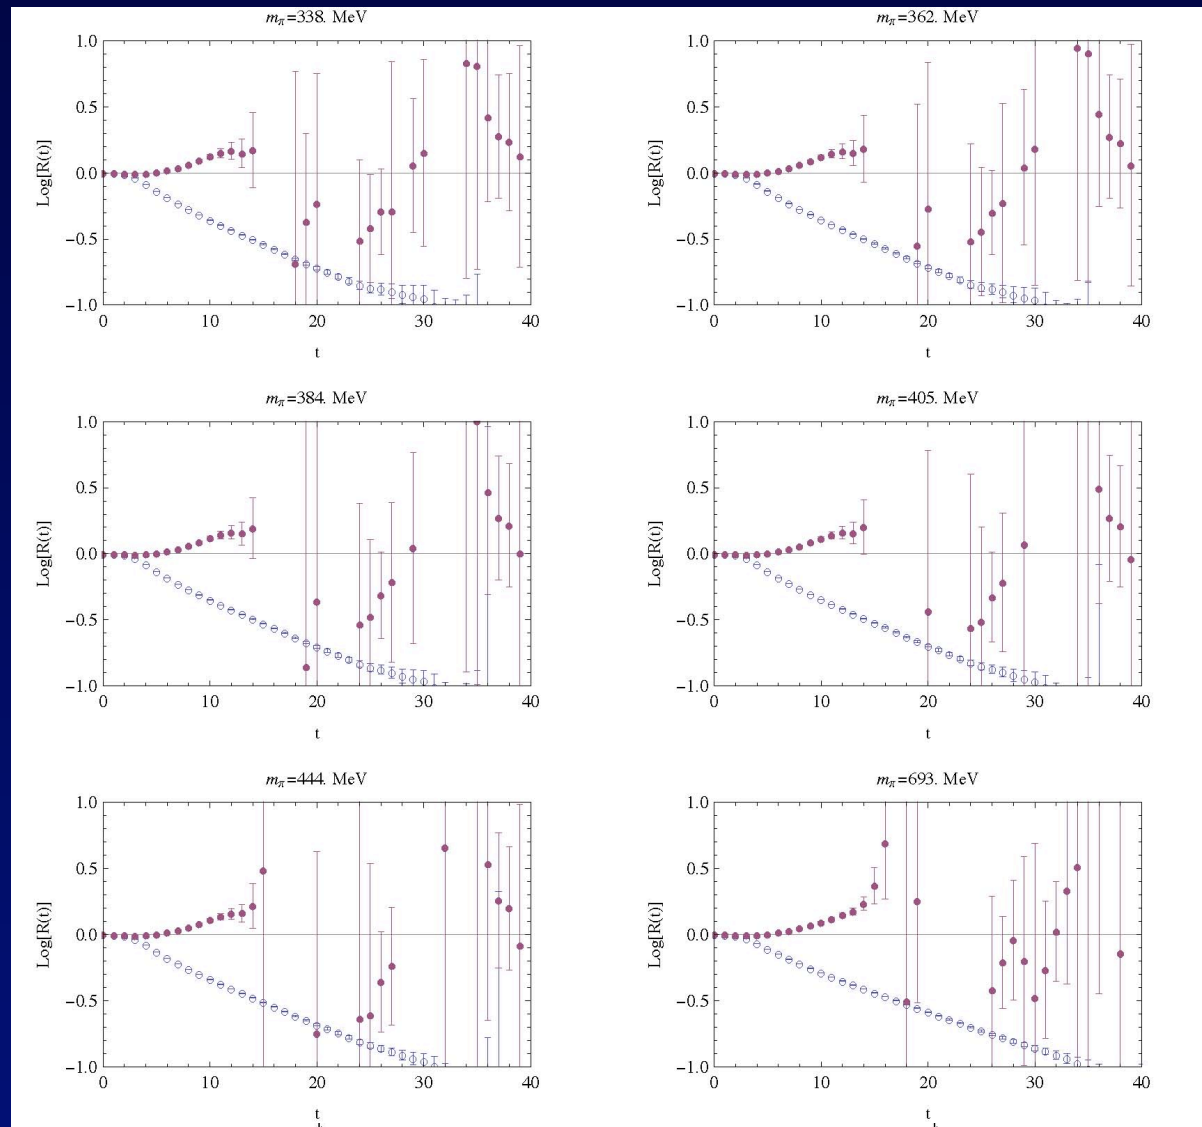

$$R(t) = \frac{G_+(B)}{G_-(B)} / \frac{G_+(-B)}{G_-(-B)}$$

$$\propto e^{-2\Delta m t}$$

$$\Delta m = [E_+(B) - E_-(B)] - [E_+(-B) - E_-(-B)]$$

$$= g \frac{eBs}{m}$$

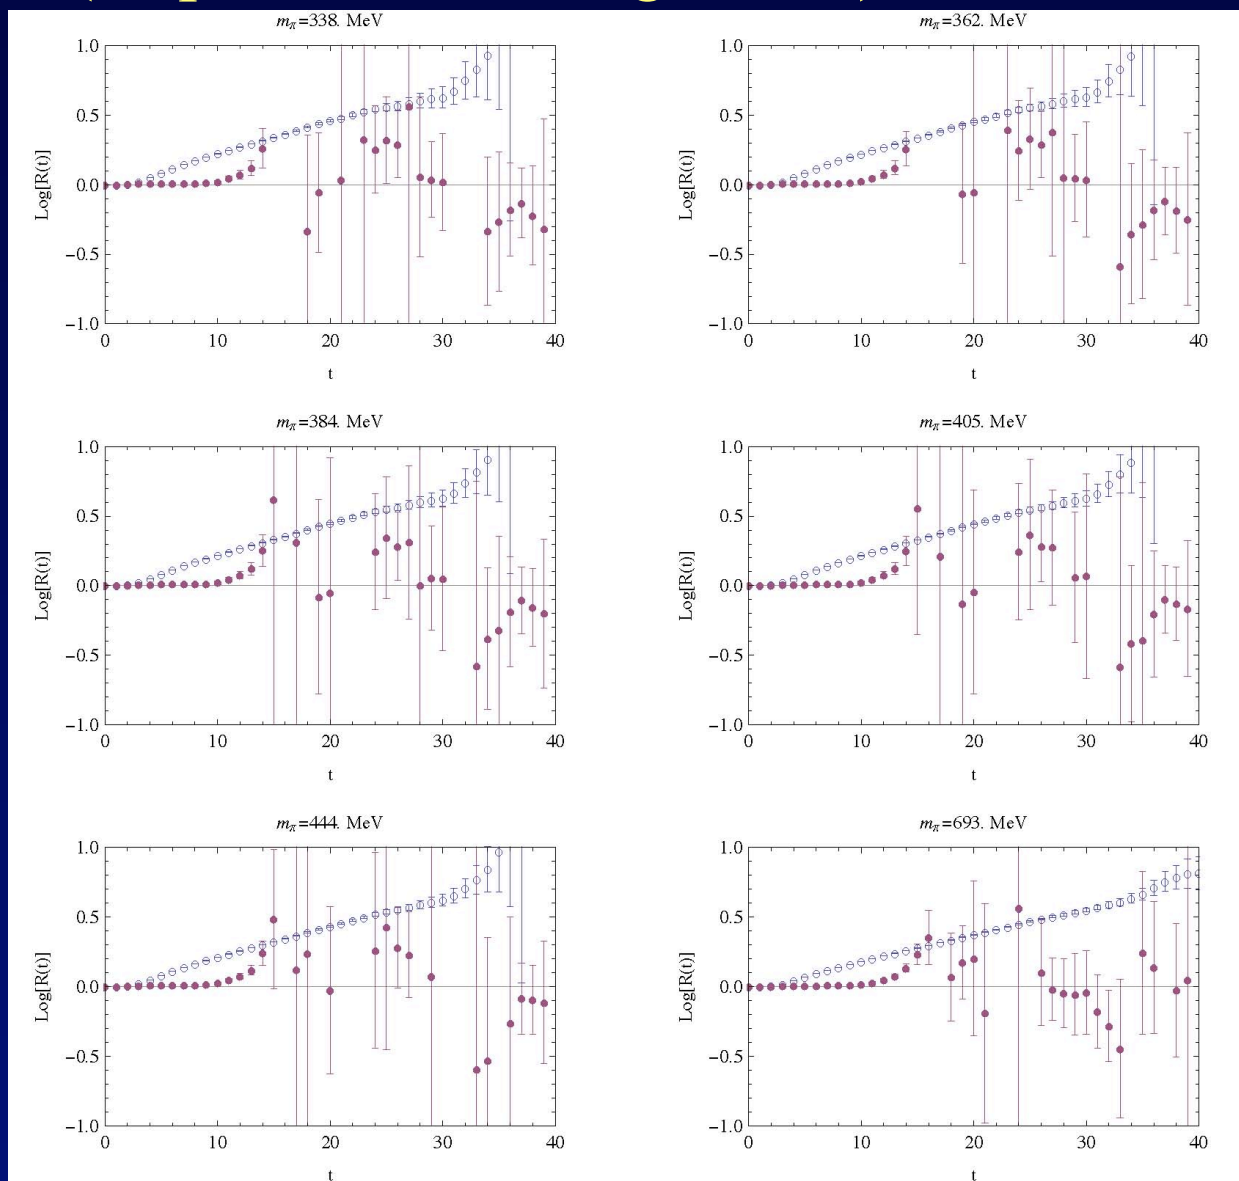

Opposite sign

Magnetic Moments for $p(1/2^+)$ and $p^*(1/2^-)$ states

Ratio of correlation functions for $n(1/2^+)$ and $n^*(1/2^-)$ (slope is related to g factor)

Same sign

Magnetic moments for $n(1/2^+)$ and $n^*(1/2^-)$ states

Masses for Octet $\Lambda_0(1/2^+)$ and $\Lambda^*_0(1/2^-)$ states

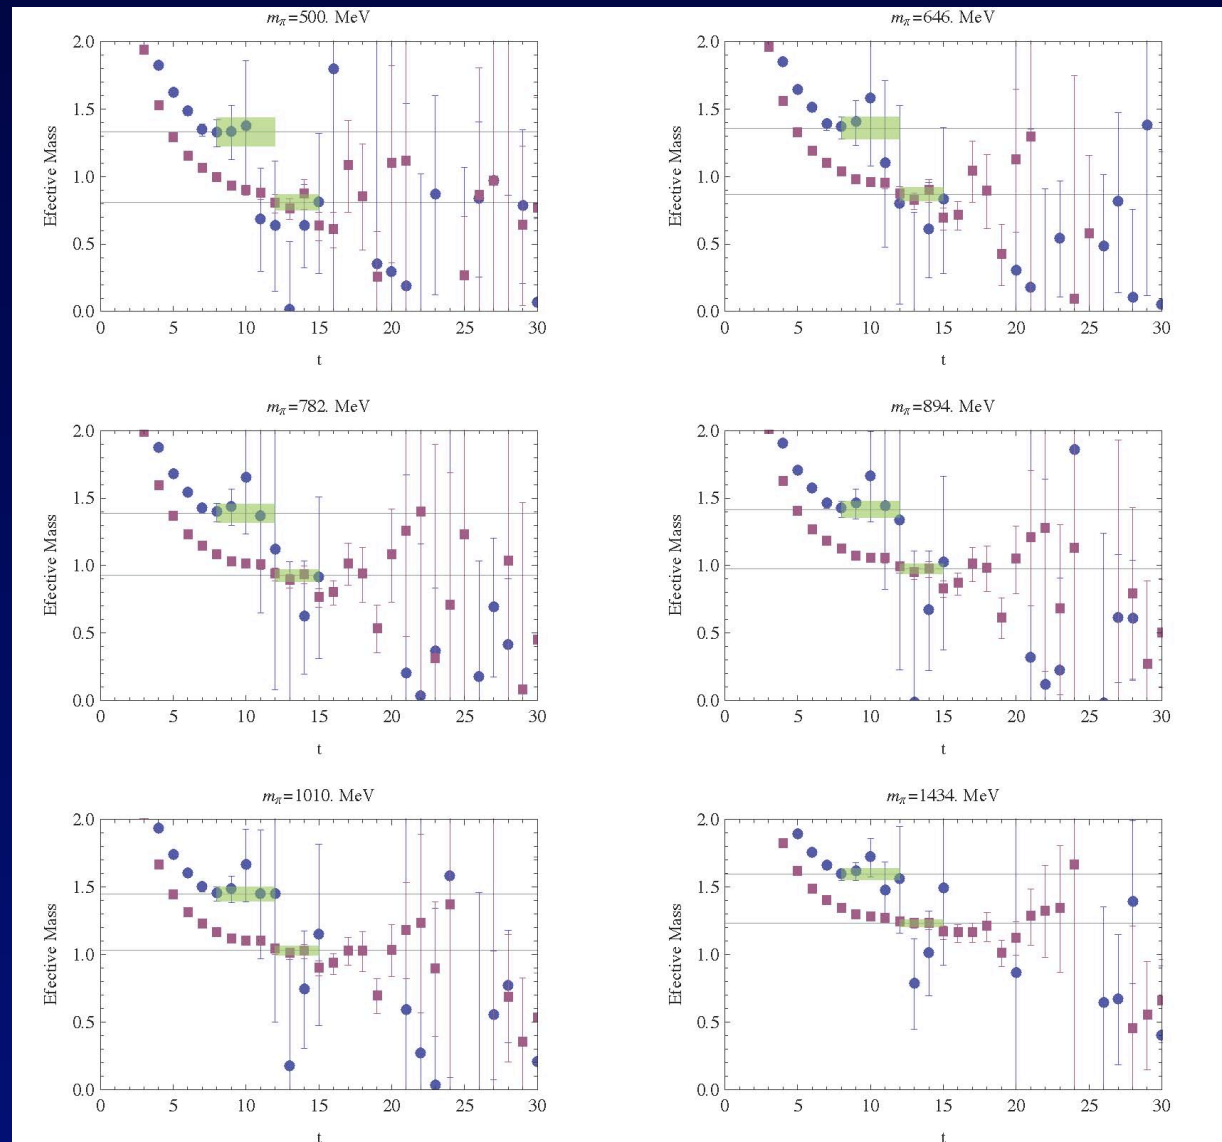

Magnetic Moments for Octet $\Lambda_0(1/2^+)$ and $\Lambda^*_0(1/2^-)$

Effective mass plots for $\Lambda_S(1/2^-)$ and $\Lambda_S^*(1/2^+)$

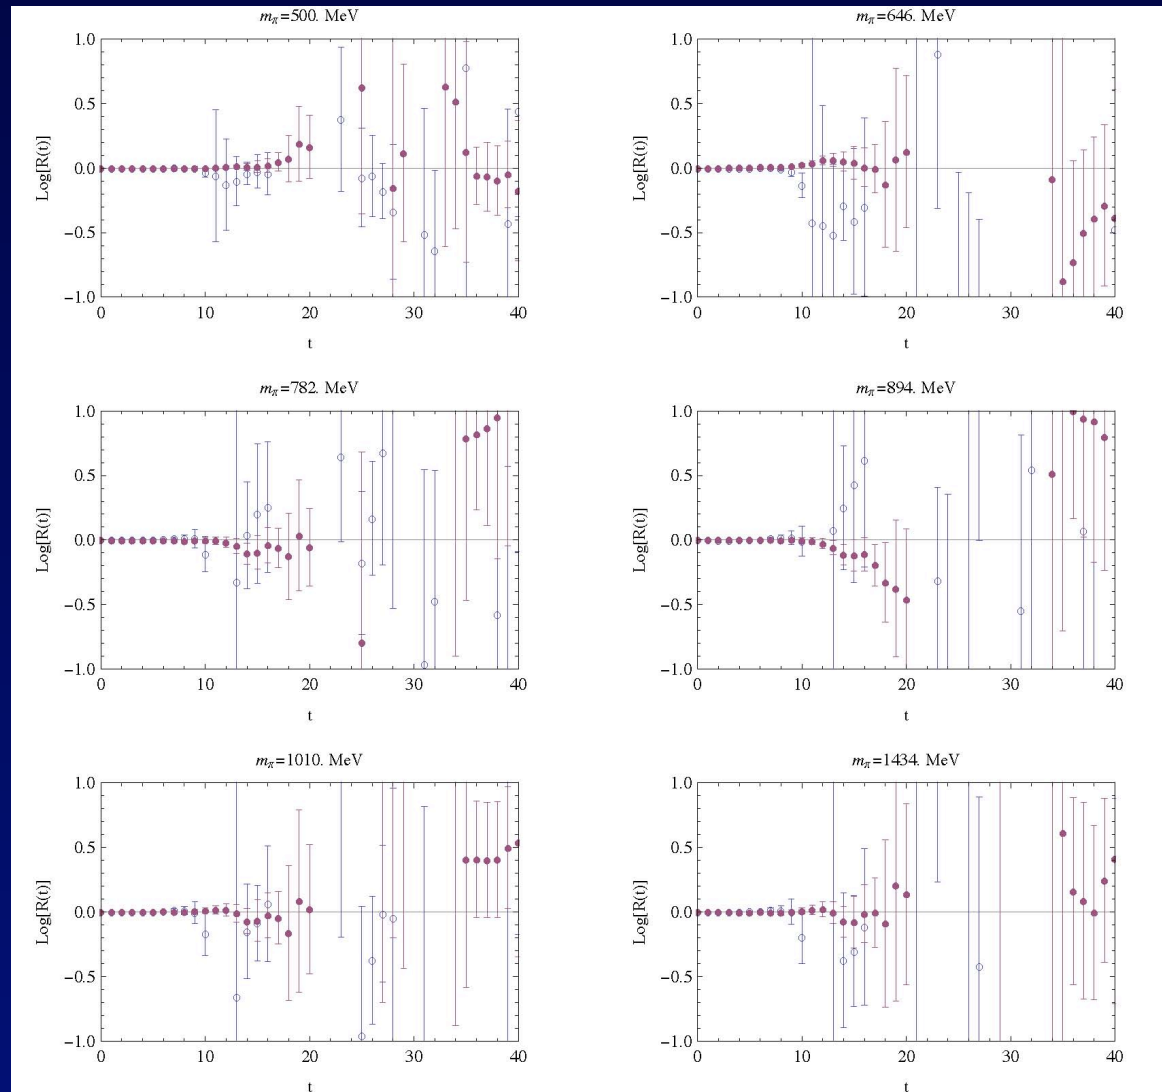

- Good signal for $\Lambda_S(1/2^-)$: fit 12-15
- Noisy signal for $\Lambda_S^*(1/2^+)$: fit 8-12

Masses for singlet $\Lambda_S(1/2^-)$ and $\Lambda^*_S(1/2^+)$ states

Ratio of correlation functions for $\Lambda_S(1/2^-)$ and $\Lambda_S^*(1/2^+)$

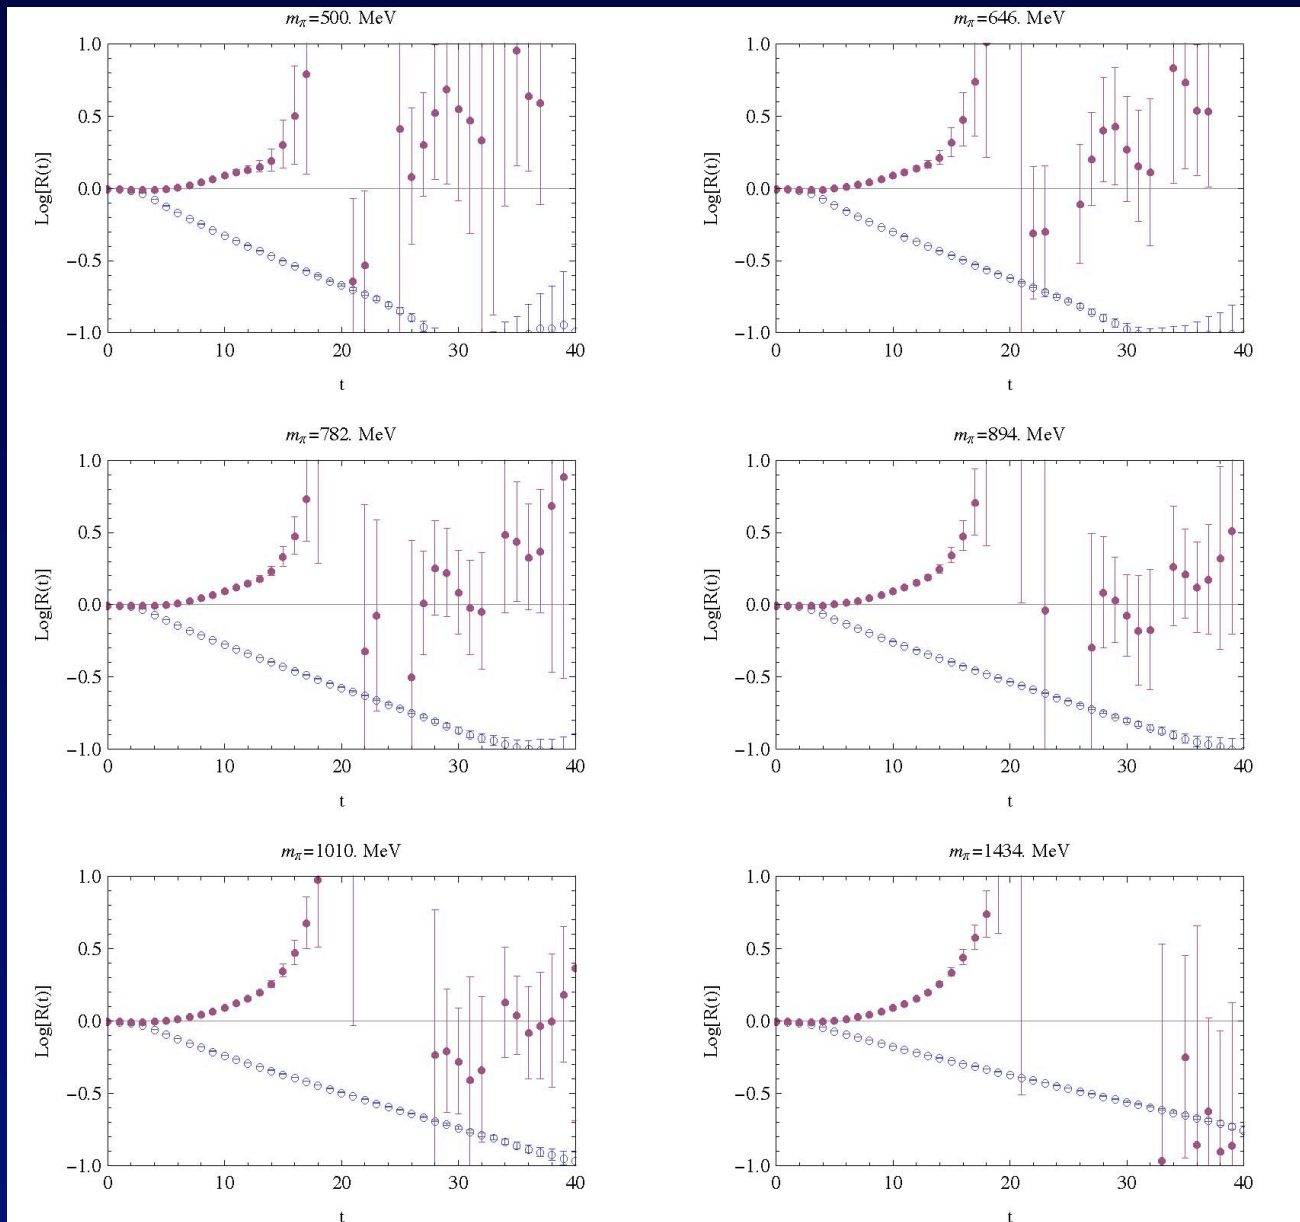

$\Lambda_S(1/2^-) \sim \text{zero}$
 $\Lambda_S^*(1/2^+) \sim \text{zero but noisy}$

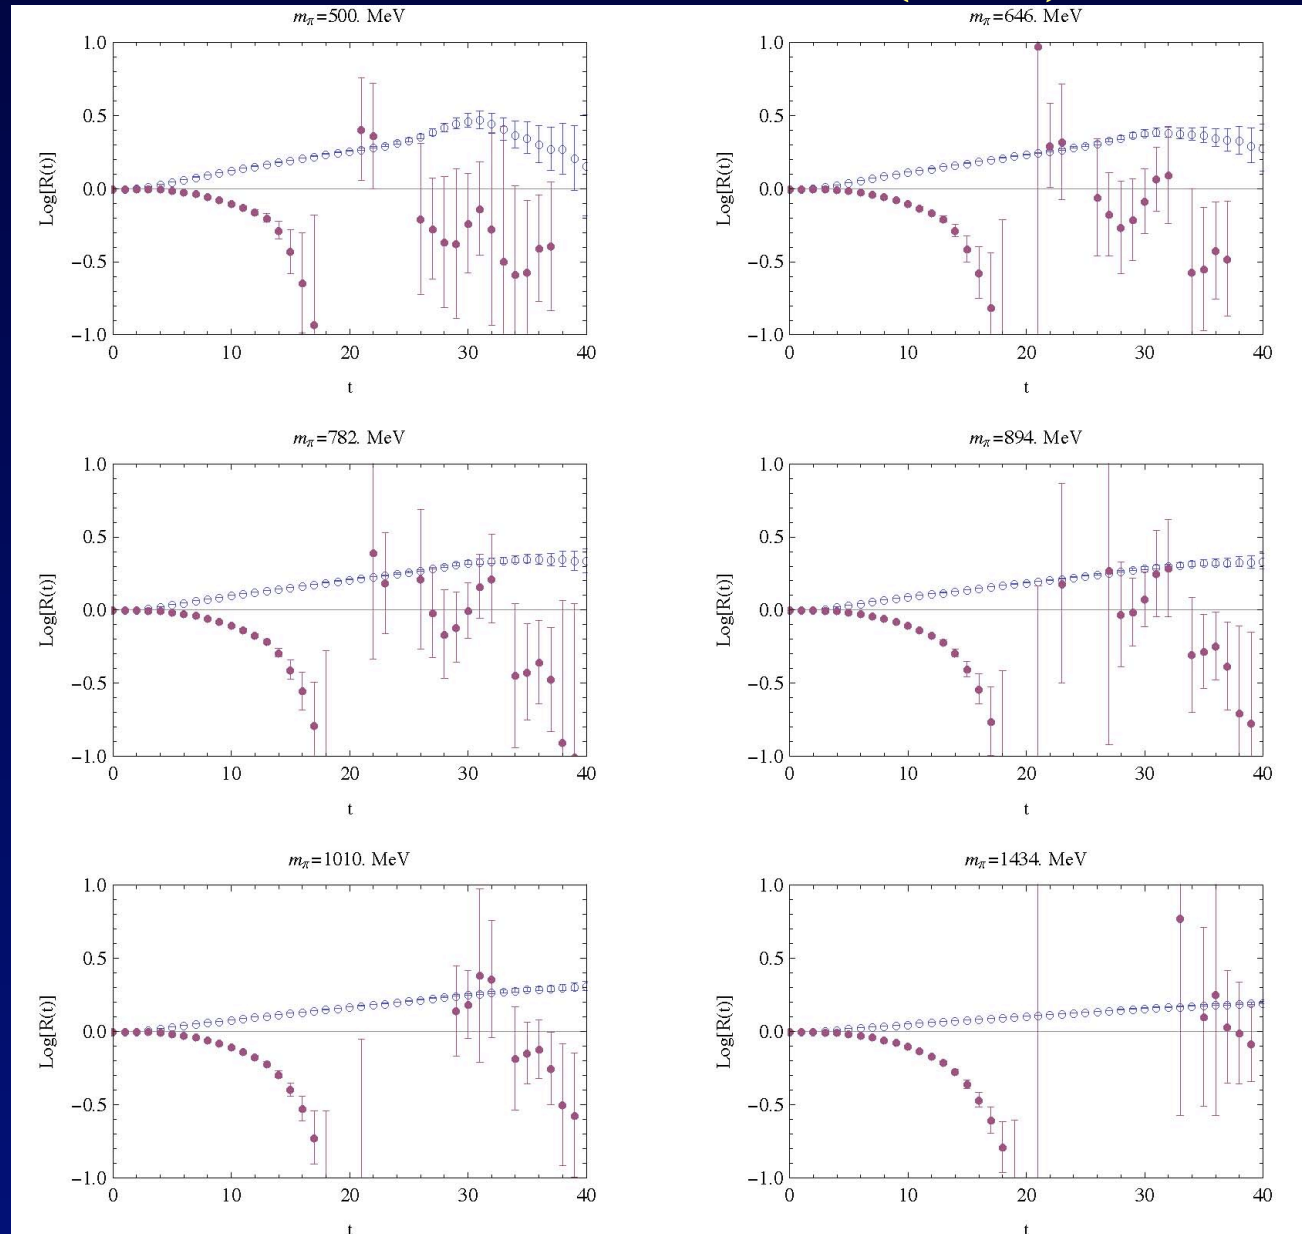

Ratio of correlation functions for $\Sigma^+(1/2^+)$ and $\Sigma^{+*}(1/2^-)$

Non-linear behavior :

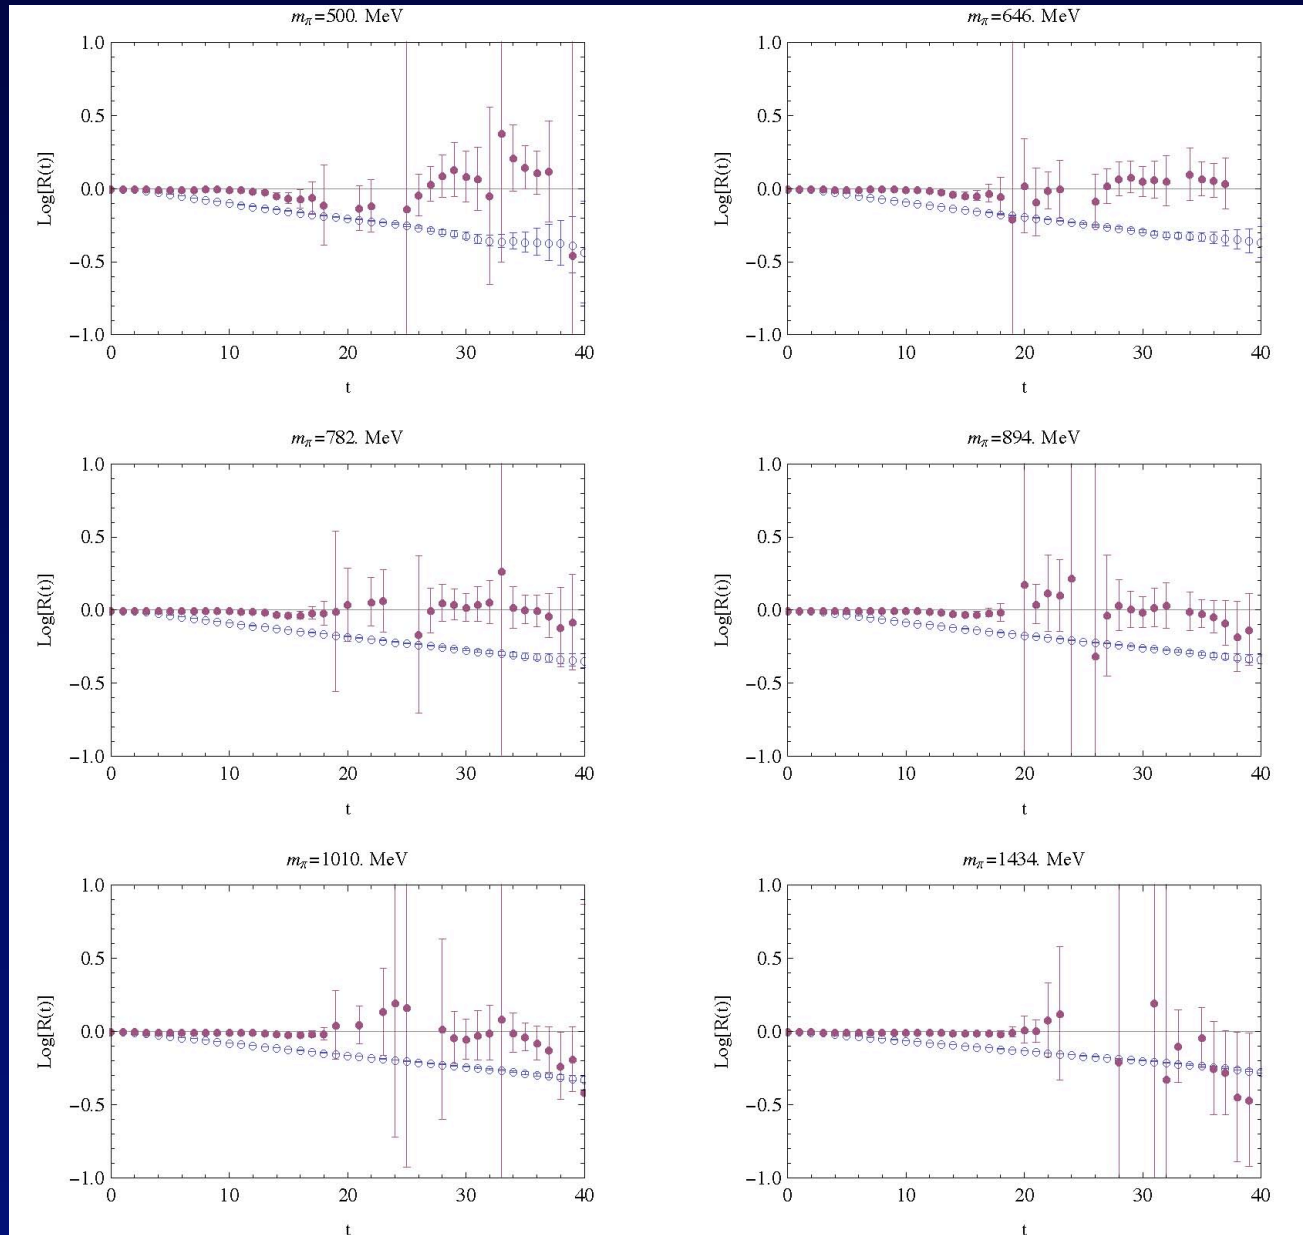

$$R(t) \propto e^{-2(\Delta mt + E_1 t^3)}$$

Ratio of correlation functions for $\Sigma^-(1/2^+)$ and $\Sigma^{*-(1/2^-)$

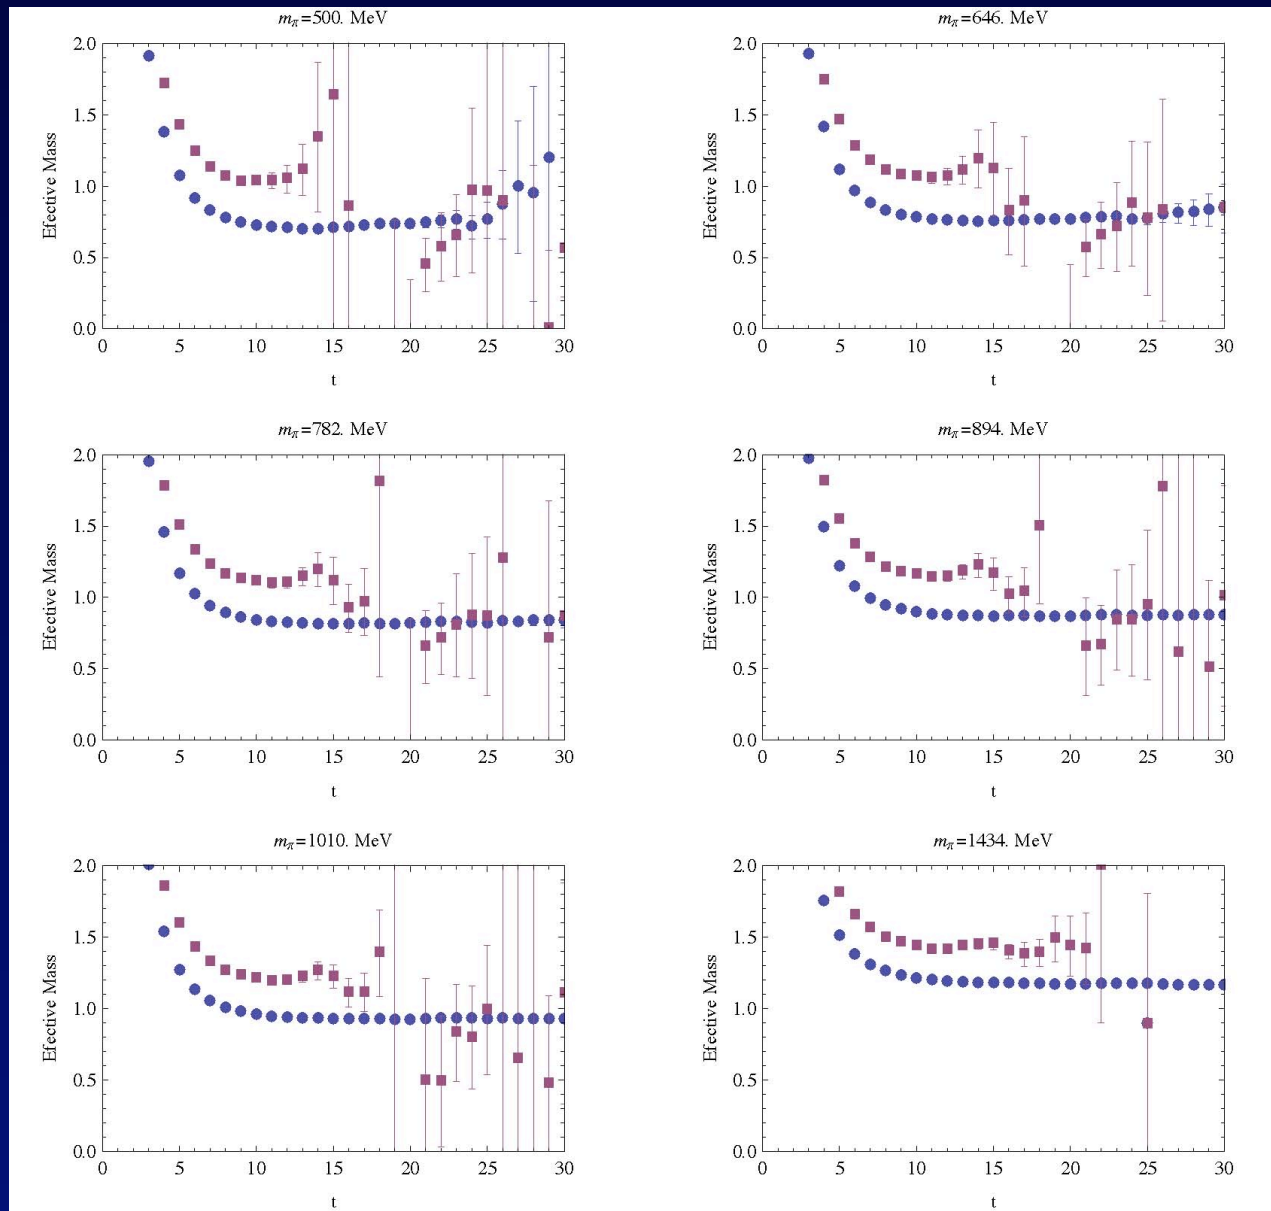

Ratio of correlation functions for $\Sigma^0(1/2+)$ and $\Sigma^{0*}(1/2-)$

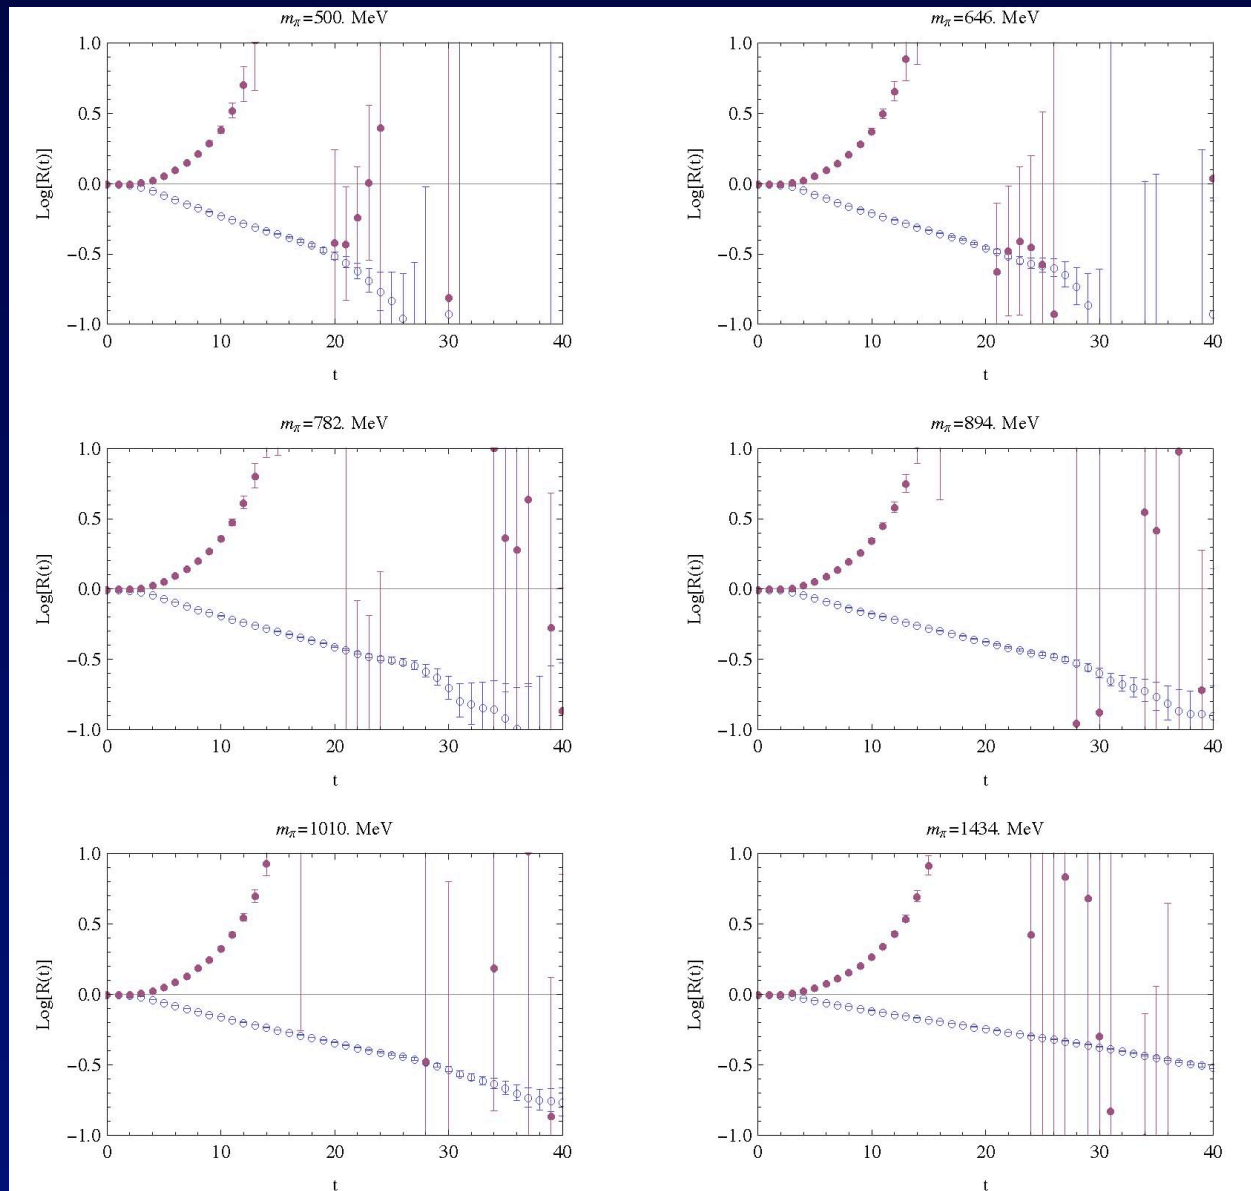

Octet Baryons

State (spin-parity)	Mass (MeV)	μ (Expt) (μ_N)	μ (Lattice QCD)	μ (Unitary χ PT)	μ (Quark Model)
p (1/2 +)	N (938)	+ 2.79	$\sim + 2.8$

Λ_O (1/2 +)	Λ (1115)	- 0.61	$\sim - 0.6$		
Λ^*_O (1/2 -)	Λ (1670)		$\sim - 0.3$	- 0.29	+ 0.28
Λ_S (1/2 -)	Λ (1405)		~ 0	0.24 to 0.45	+ 0.04
Λ^*_S (1/2 +)	Λ (\sim 2400)		~ 0 (noisy)		
Σ^+ (1/2 +)	Σ (1119)	+ 2.45	$\sim + 2.9$		
Σ^{+*} (1/2 -)			-		
Σ^0 (1/2 +)		+ 0.65	$\sim + 0.8$		
Σ^{0*} (1/2 -)			$\sim - 0.5$		
Σ^- (1/2 +)		- 1.16	$\sim - 1.5$		
Σ^{*-} (1/2 -)			negative		

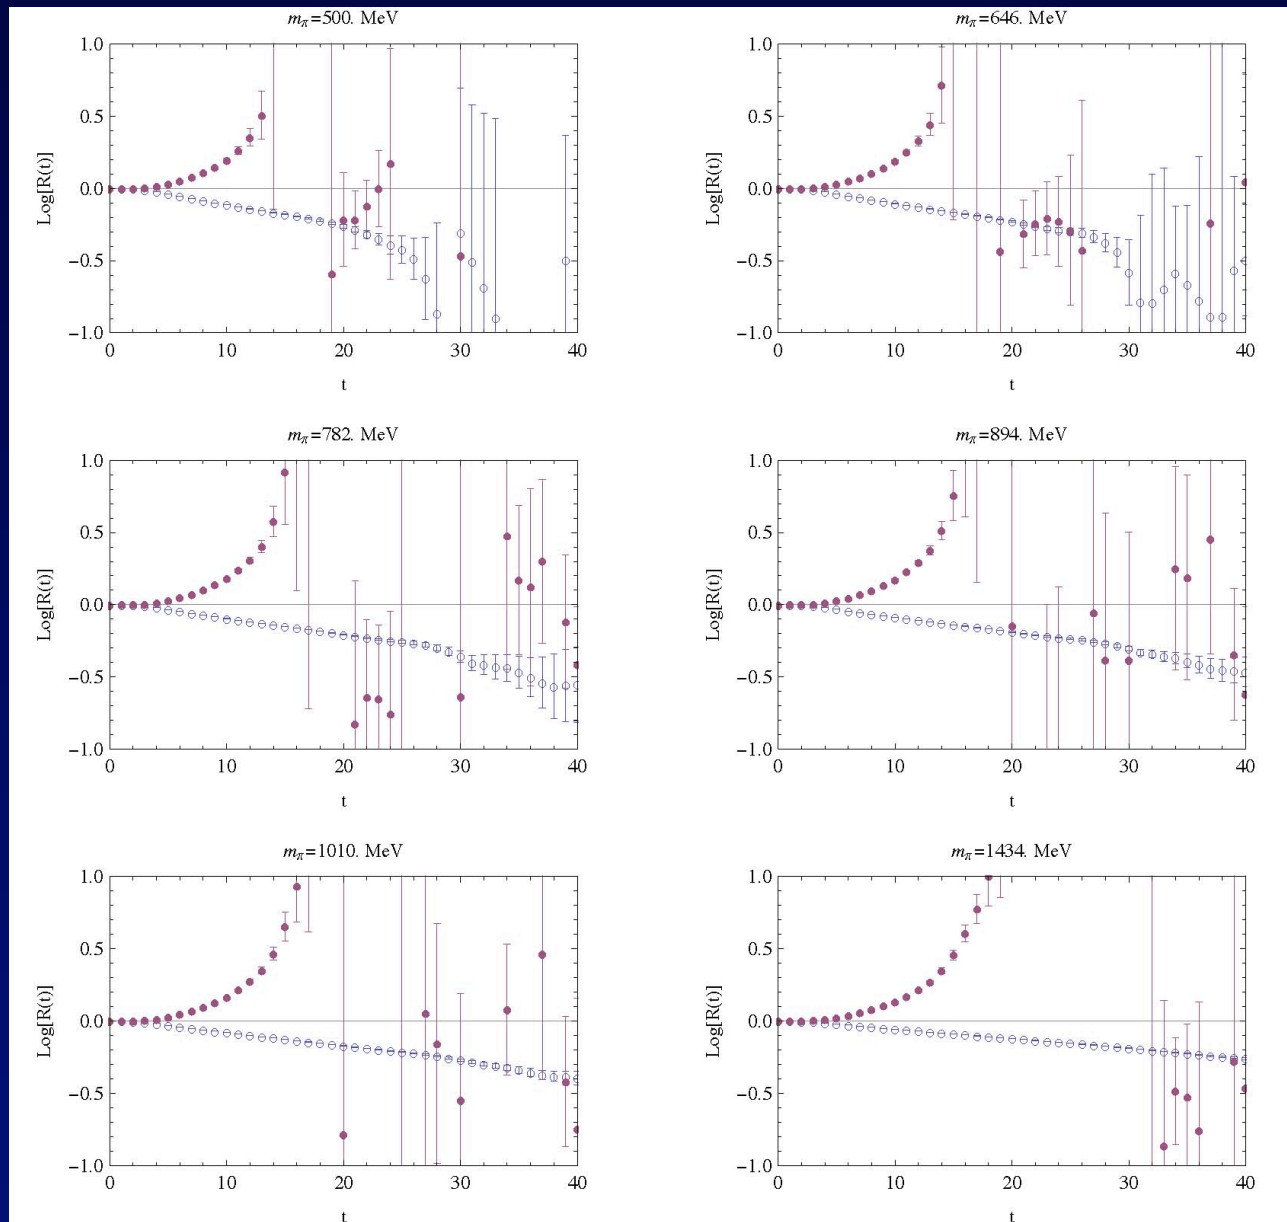

Effective mass plots for $\Delta(3/2^+)$ and $\Delta^*(3/2^-)$

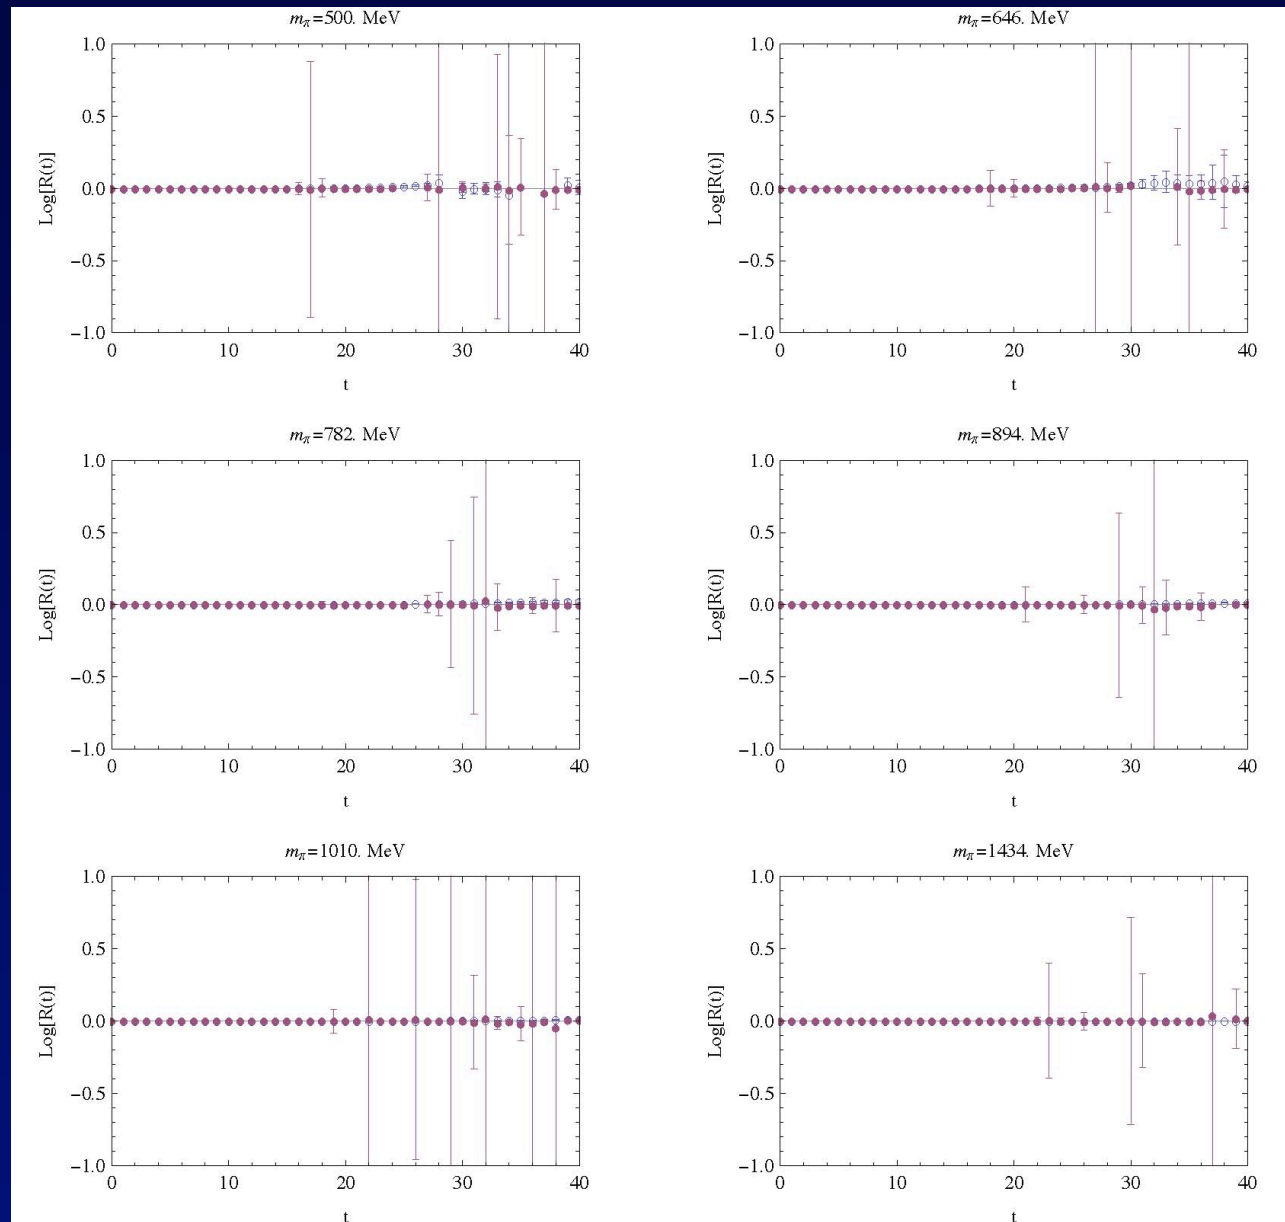

Ratio of correlation functions for $\Delta^{++}(3/2+)$ and $\Delta^{++*}(3/2-)$

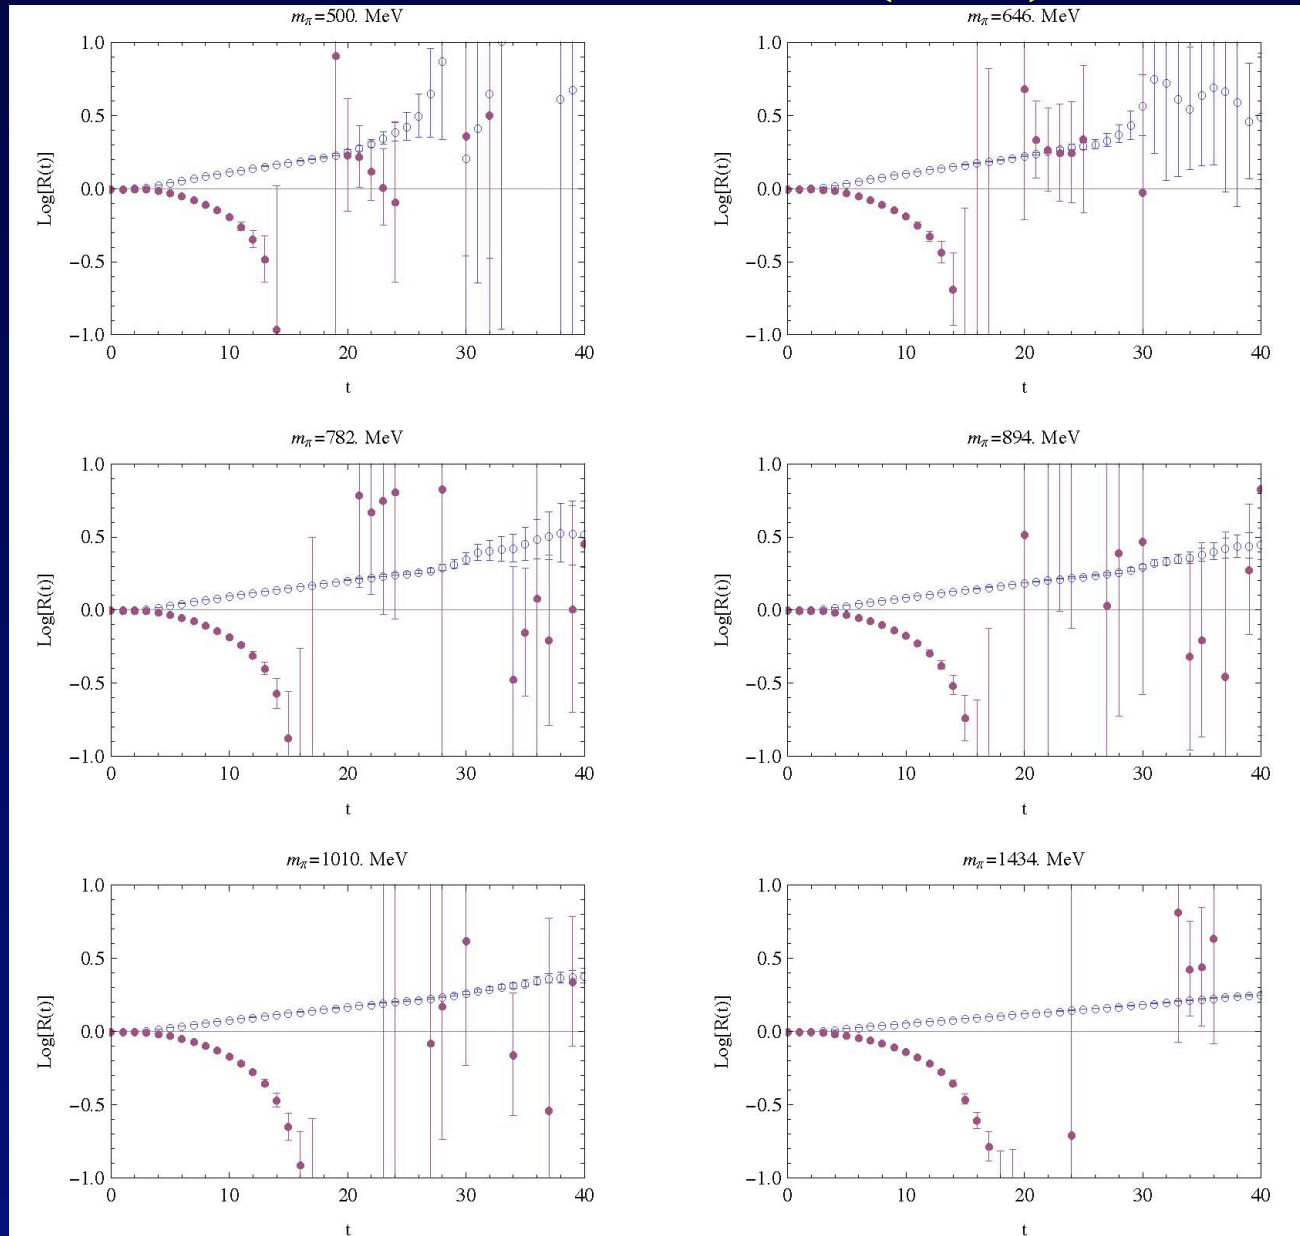

Ratio of correlation functions for $\Delta^+(3/2^+)$ and $\Delta^{+*}(3/2^-)$

Ratio of correlation functions for $\Delta^0(3/2^+)$ and $\Delta^0(3/2^-)$

Ratio of correlation functions for $\Delta^-(3/2^+)$ and $\Delta^{*-(3/2^-)$

Delta Baryons

State (spin-parity)	Mass (MeV)	μ (Expt) (μ_N)	μ (Lattice QCD)
Δ^{++} (3/2 +)	Δ (1232)	2.5 to 5.5	$\sim + 5.0$
$\Delta^{++ *}$ (3/2 -)	Δ (1700)		negative
Δ^+ (3/2 +)			$\sim + 2.5$
$\Delta^+ *$ (3/2 -)			negative
Δ^0 (3/2 +)			zero
$\Delta^0 *$ (3/2 -)			zero
Δ^- (3/2 +)			$\sim - 3.0$
$\Delta^- *$ (3/2 -)			positive

Conclusion

- The background field method is a robust probe of hadron internal structure.
- Comparison study of magnetic moments for positive- and negative-parity states offers interesting insight into underlying quark-gluon dynamics
 - Good signal for positive-parity baryon states
 - Non-linear behavior is observed for negative-parity counterparts.
- **Better isolation of negative-parity signals**
 - smearing, anisotropic lattice, etc
 - use of chiral quarks (overlap, DW) for small pion masses
 - finite volume effects

Baryon Interpolating Fields

$$I(J^P) = \frac{1}{2}(\frac{1}{2}^+): \quad \chi_1 = \varepsilon_{abc} (u^{aT} C \gamma_5 d^b) u^c \quad \chi_2 = \varepsilon_{abc} (u^{aT} C d^b) \gamma_5 u^c$$

Negative parity (multiply by γ_5): $\chi_1^- = \gamma_5 \chi_1$, $\chi_2^- = \gamma_5 \chi_2$

Non-relativistic limit:

$\chi_1 \rightarrow$ (big - big - big) $\rightarrow O(1)$ (couples to nucleon)

$\chi_2 \rightarrow$ (big - small - small) $\rightarrow O(p^2 / E^2)$ (couples to ?)

$\chi_1^- \rightarrow$ (big - big - small) $\rightarrow O(p / E)$ (couples to $\frac{1}{2}^-$ state)

$\chi_2^- \rightarrow$ (big - small - big) $\rightarrow O(p / E)$ (couples to $\frac{1}{2}^-$ state)

In the spectrum : $N^*(1535) \frac{1}{2}^-$ and $N^*(1650) \frac{1}{2}^-$.

Caution: Near the chiral limit, the upper and lower components become equally important.
