(\*) Main topics of these lectures

- **p-p<sup>(\*)</sup>**, p-A and A-A collider
  - 2009-2012: Run1  $\sqrt{s} = 7-8$  TeV
  - 2015-2019: Run2  $\sqrt{s} = 13$  TeV
- Seven experiments: ALICE, **ATLAS**, **CMS<sup>(\*)</sup>**, LHCb, LHCf, TOTEM and MoEDAL
- 40 MHz (25 ns) collision rate

Quantity
Circumference
Dipole operating temperature
Number of magnets
Number of main dipoles
Number of main quadrupoles
Number of RF cavities
Nominal energy, protons
Nominal energy, ions
Nominal energy, protons collisions
No. of bunches per proton beam
No. of protons per bunch (at start)
Number of turns per second
Number of collisions per second

Number
26 659 m
1.9 K (-271.3°C)
9593
1232
392
8 per beam
6.5 TeV
2.56 TeV/u (energy per nucleon)
13 TeV
2808
$1.2 \times 10^{11}$
11245
1 billion

**2556 achieved**

**88.9  $\mu$ s**

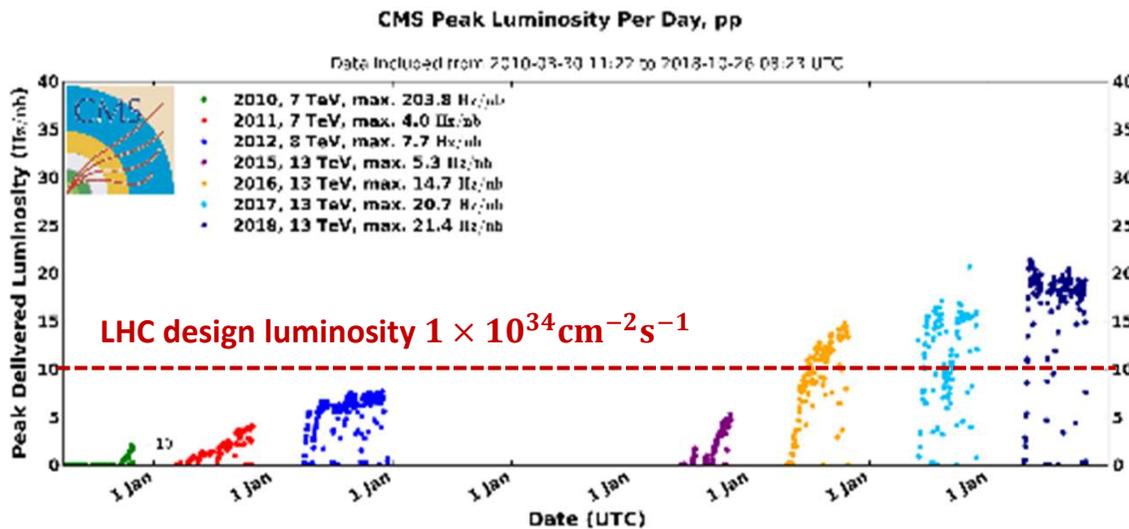

## Luminosity $\mathcal{L}$

$$\frac{dN}{dt} = \sigma \mathcal{L}$$

- rate of interactions

$$\mathcal{L} = \frac{n_b f_{rev} N^2}{4\pi \sigma_x \sigma_y}$$

- $n_b$  number of bunches
- $f_{rev}$  revolution frequency
- $N$  particles per bunch
- $\sigma_{x,y}$  beam size at interaction point

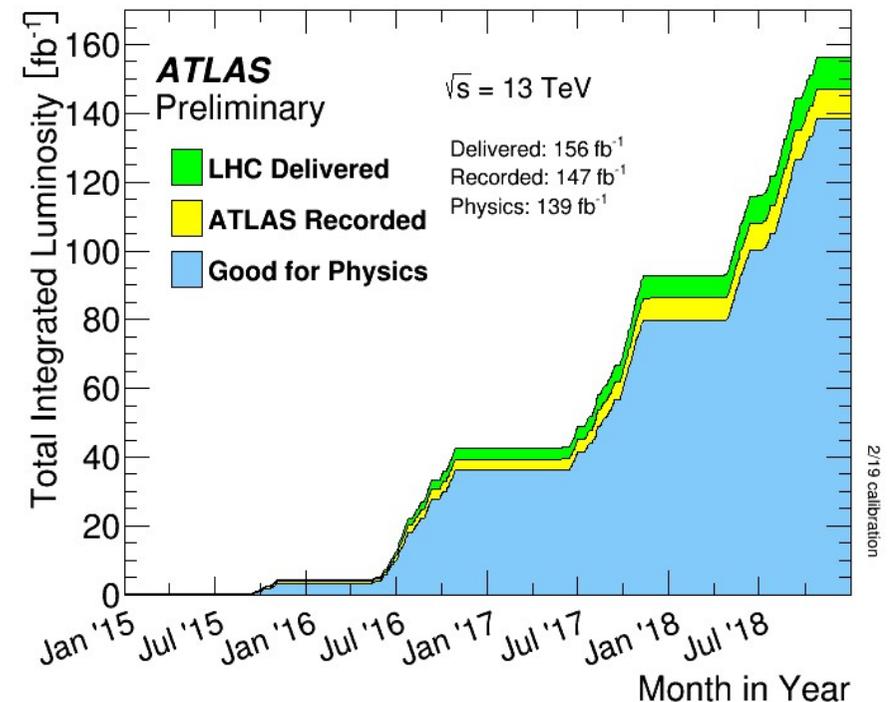

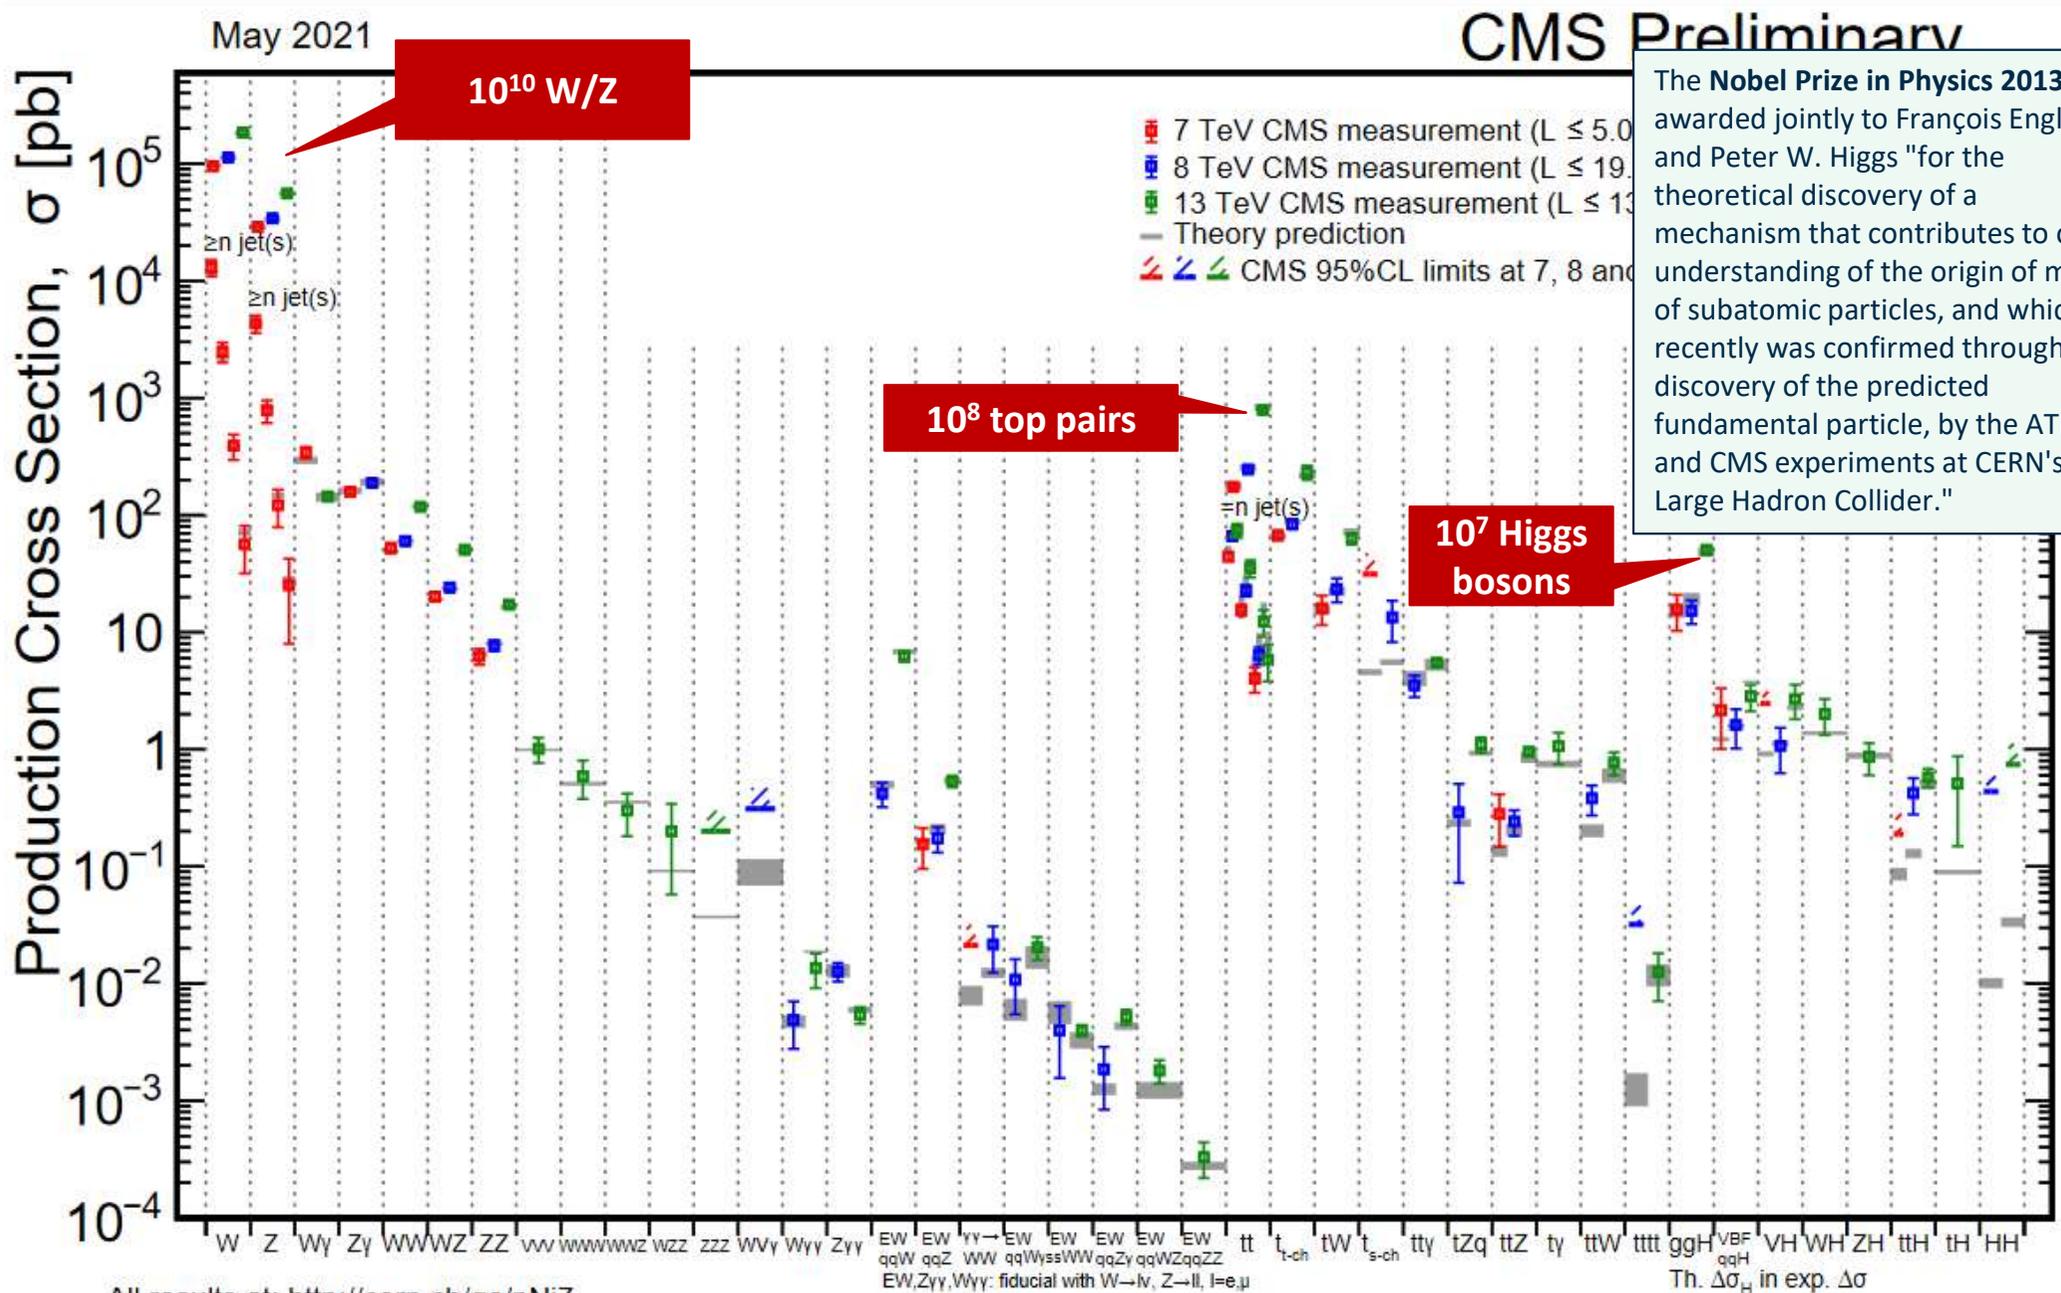

## Integrated luminosity

$$N = \sigma \int \mathcal{L} dt$$

- total number of produced events
- determines the physics reach of the experiment

At the end of Run2  $\sim 150 \text{ pb}^{-1}/\text{experiment}$

All results at: <http://cern.ch/go/pNj7>

# Beyond the Standard Model

## ATLAS SUSY Searches\* - 95% CL Lower Limits

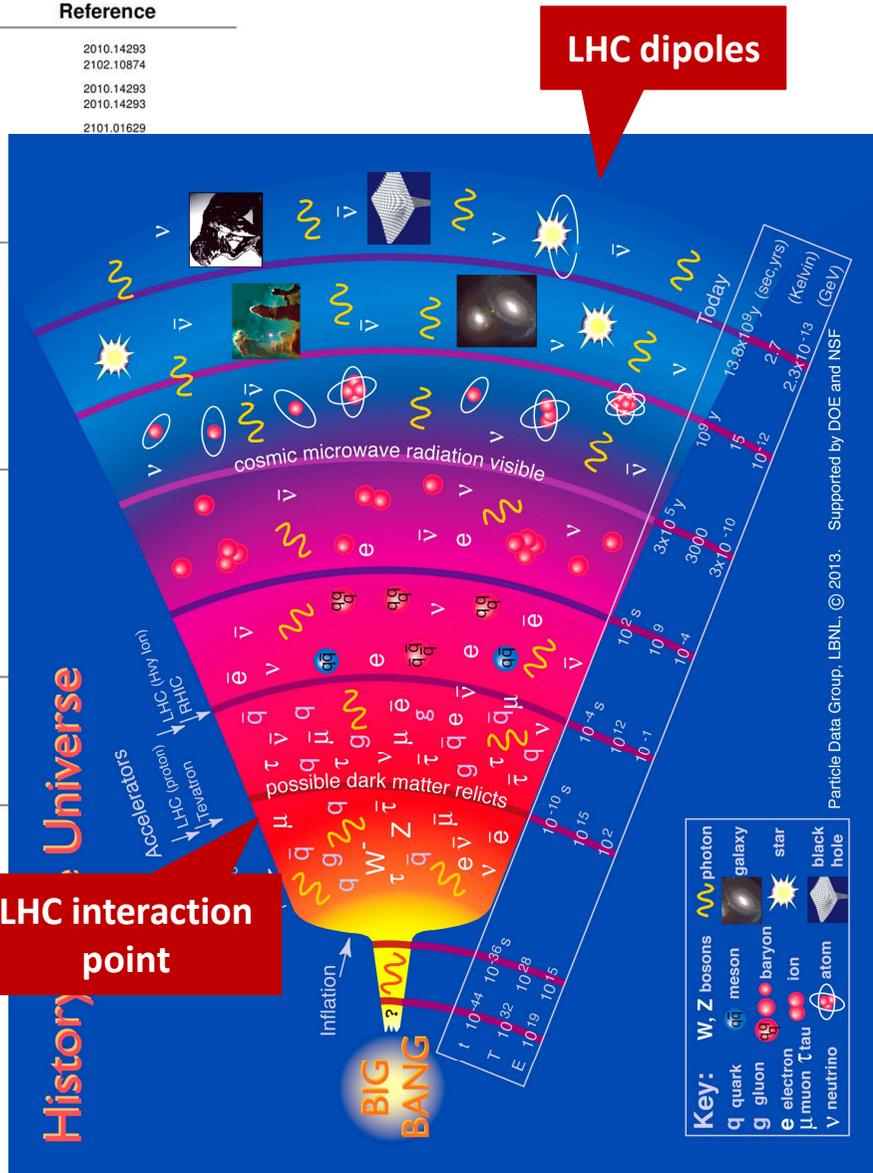

March 2021

ATLAS Preliminary

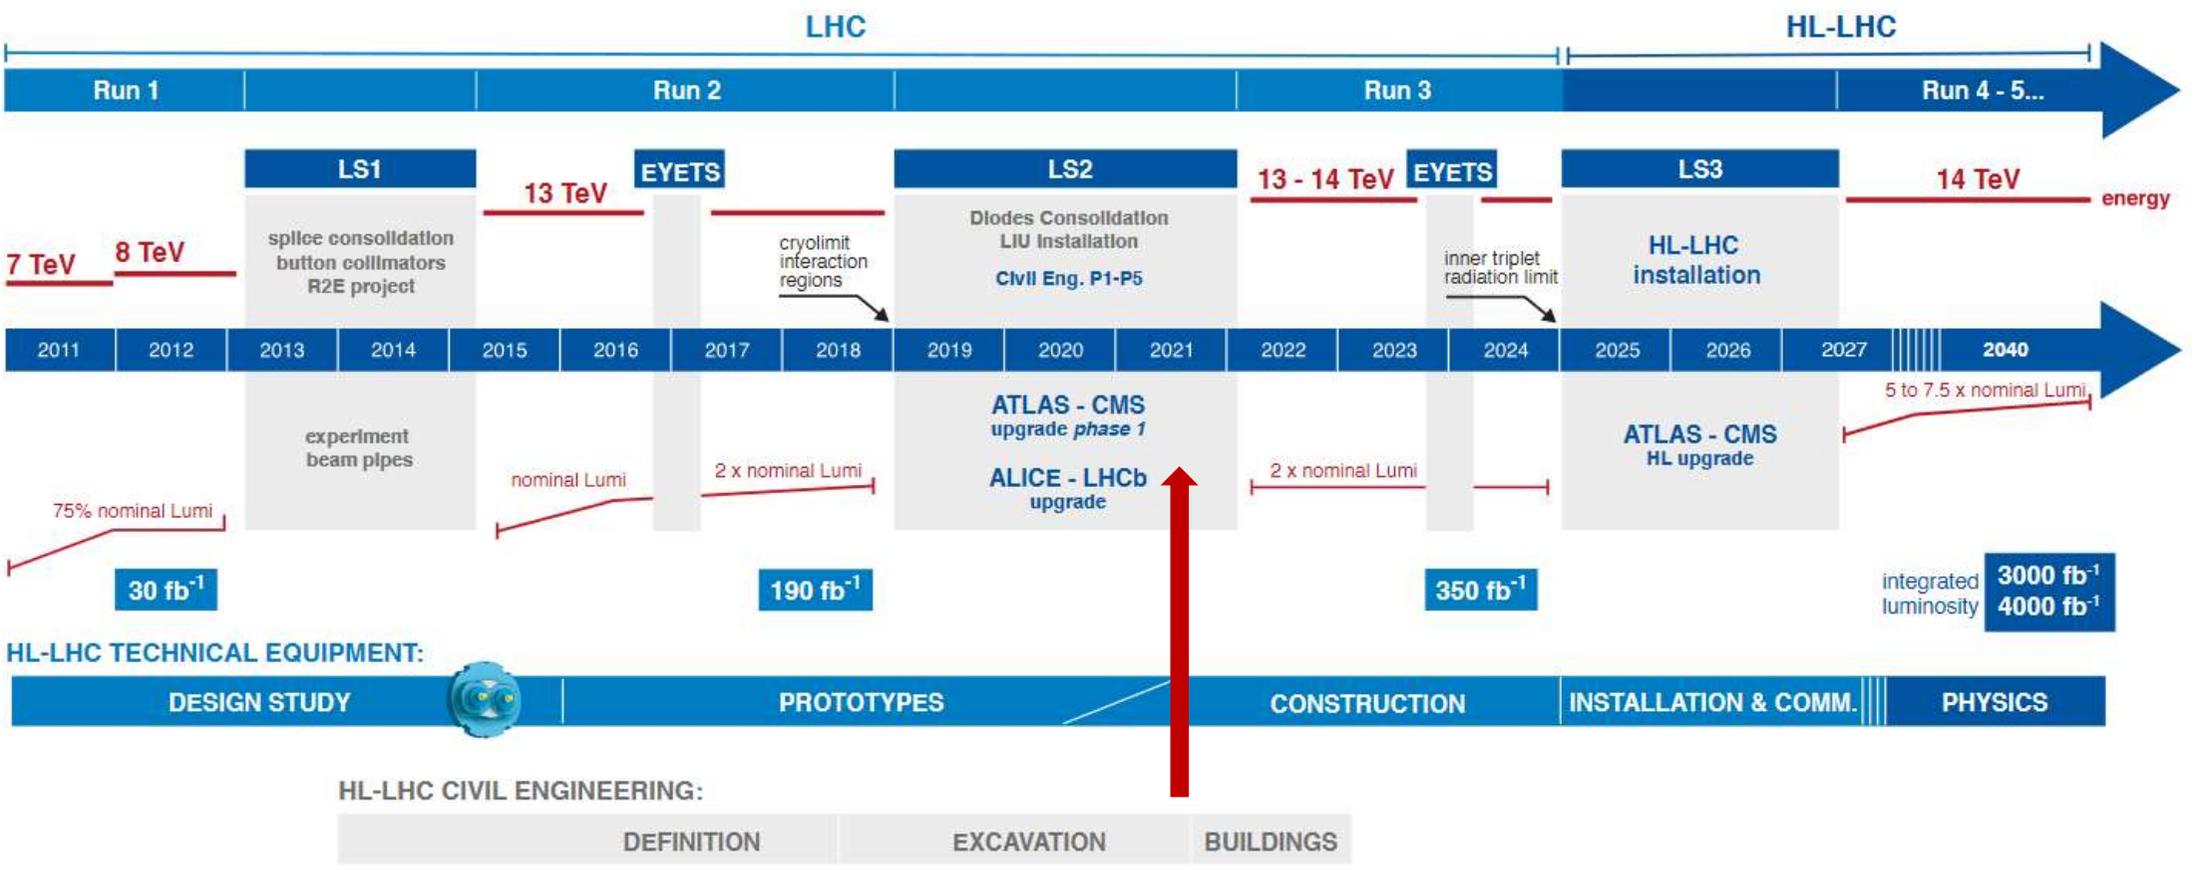

$\sqrt{s} = 13$  TeV

\*Only a selection of the available mass limits on new states or phenomena is shown. Many of the limits are based on simplified models, c.f. refs. for the assumptions made.

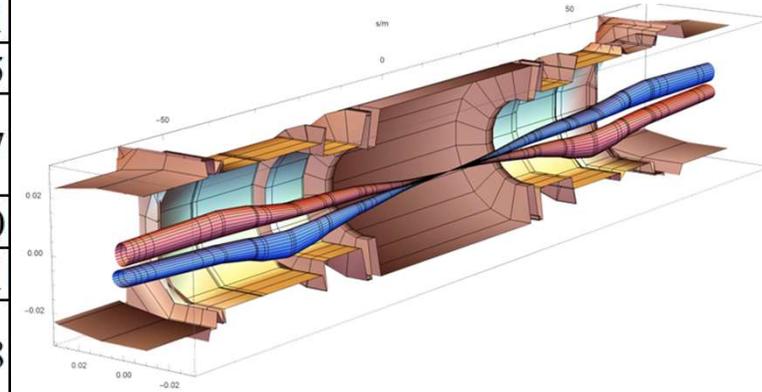

## LHC / HL-LHC Plan

# Coordinate system

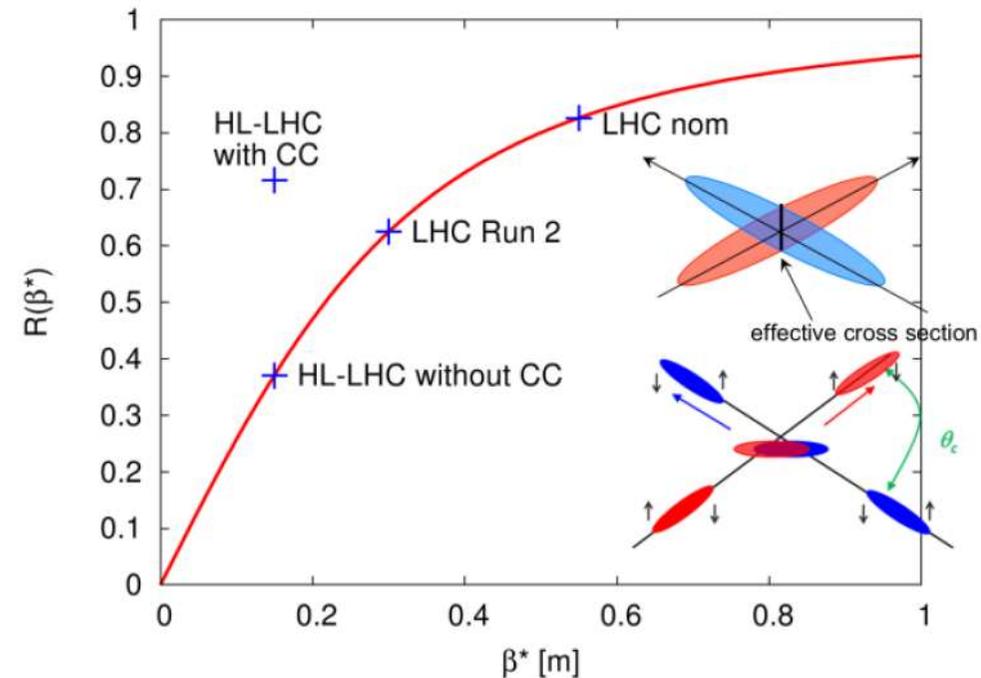

Parameter	Nominal LHC (design report)	HL-LHC 25 ns (standard)
Number of bunches	2808	2760
Beam current (A)	0.58	1.1
Minimum $\beta^*$ (m)	0.55	0.15
Peak luminosity with crab cavities $L_{\text{peak}} \times R_1/R_0$ ( $10^{34} \text{ cm}^{-2} \text{ s}^{-1}$ )	(1.18)	17
Levelled luminosity for $\mu = 140$ ( $10^{34} \text{ cm}^{-2} \text{ s}^{-1}$ )	-	5.0
Events/crossing $\mu$ (with levelling and crab cavities)	27	131
Maximum line density of pile-up events during fill (events/mm)	0.21	1.28

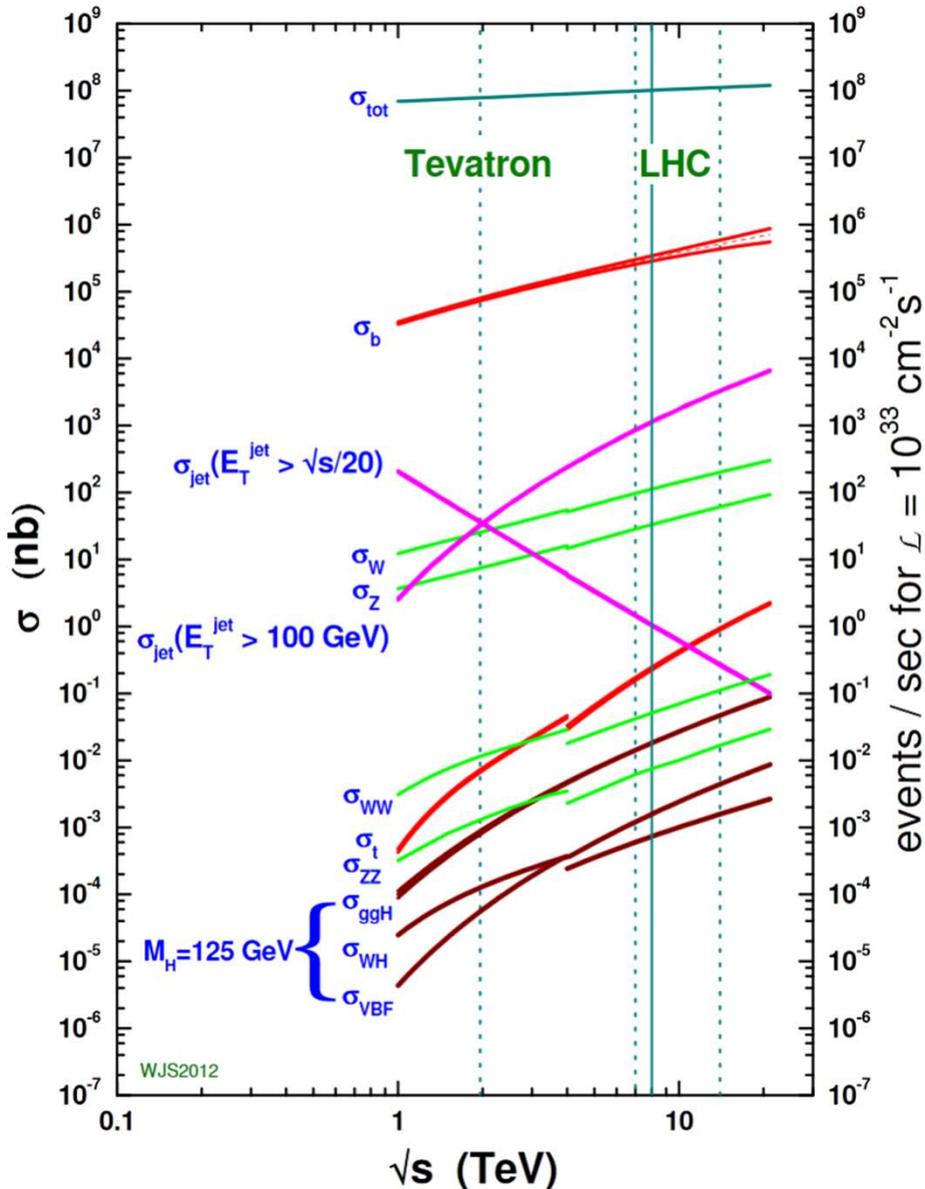

$$\mathcal{L} = \frac{n_b f_{\text{rev}} N^2}{4\pi\sigma_x\sigma_y} \Leftrightarrow \frac{n_b f_{\text{rev}} N^2}{4\pi\varepsilon_n\beta^*/\gamma} R, \quad R = \left(1 + \frac{\theta_c \sigma_z}{\sigma_{x,y}}\right)^{-\frac{1}{2}}$$

- $\gamma$  relativistic factor
- $\varepsilon_n$  normalized emittance
- $\beta^*$  beta function at the collision point
- $\theta_c$  crossing angle
- $\sigma_z$  longitudinal bunch length

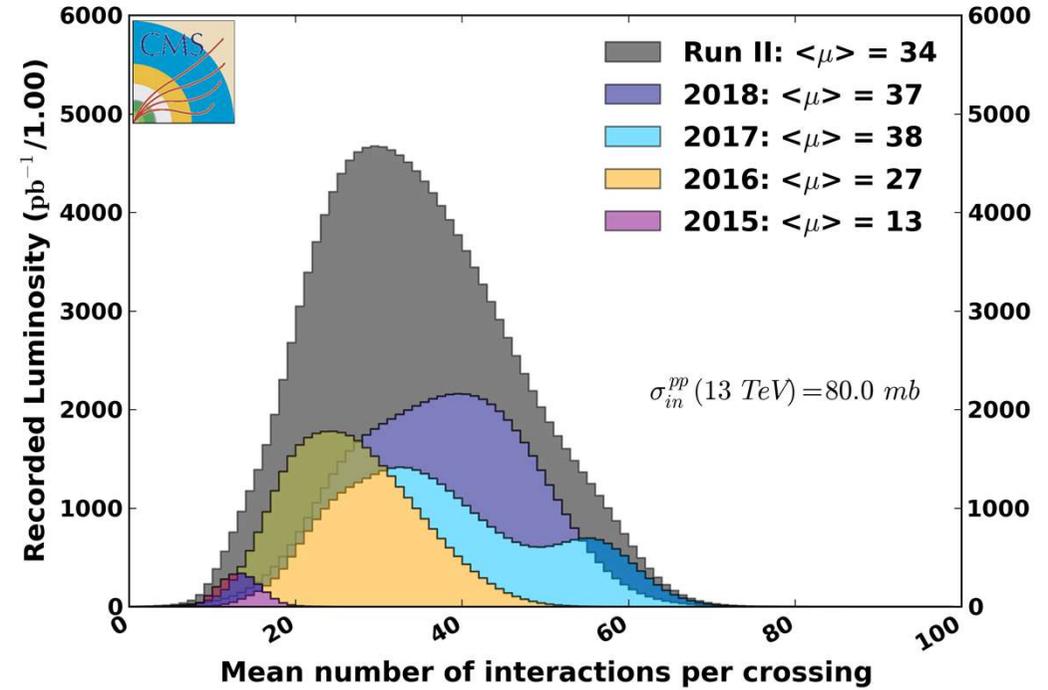

# Luminosity: pile-up

## proton - (anti)proton cross sections

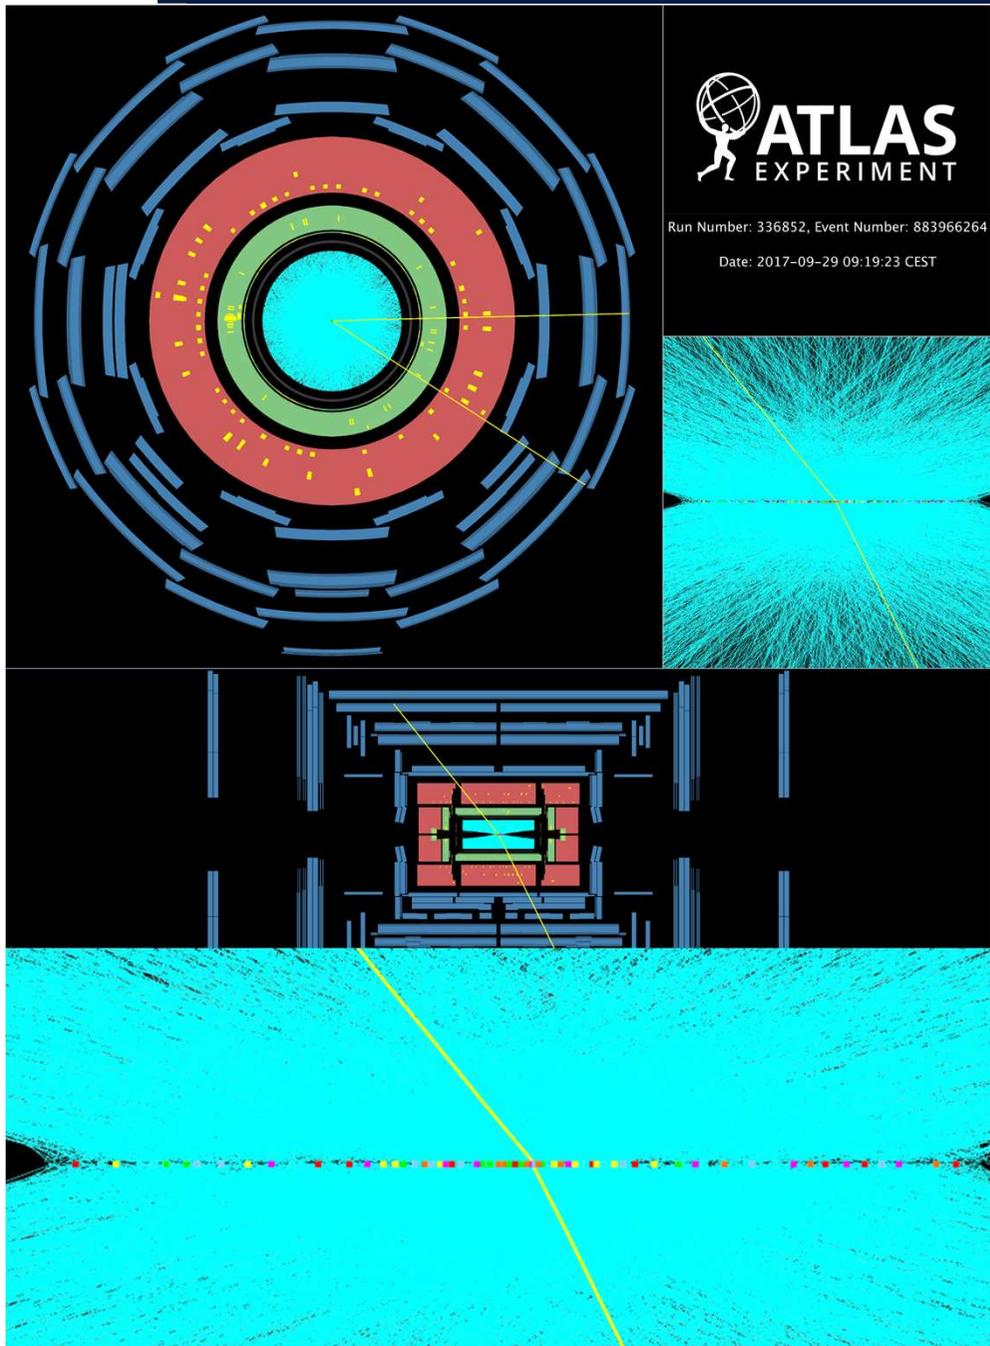

CMS Average Pileup (pp,  $\sqrt{s}=13 \text{ TeV}$ )

- Total pp cross section: 80 mb
  - For  $1 \times 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$ ,  $10^9$  events/s
  - With 25 ns collision rate: 25 events/collision

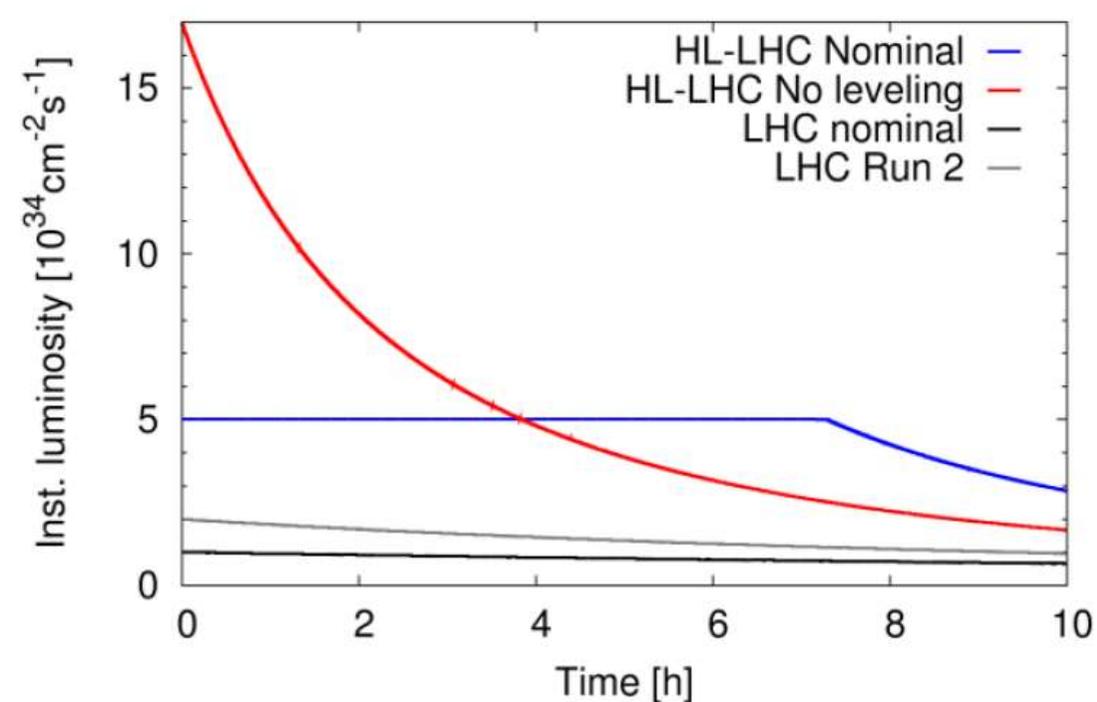

# Luminosity: pile-up

**ATLAS**  
EXPERIMENT

Run Number: 336852, Event Number: 883966264

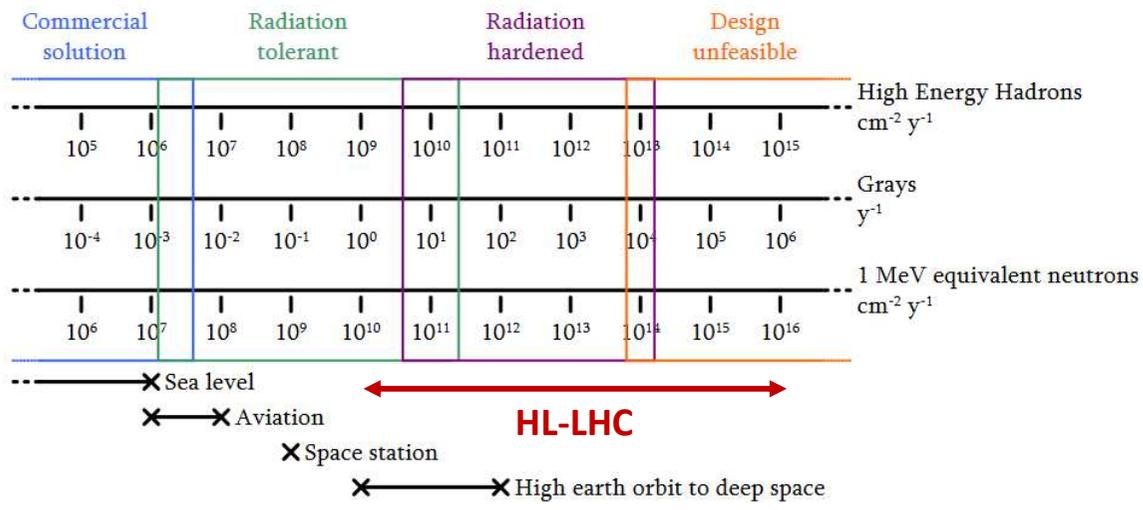

Date: 2017-09-29 09:19:23 CEST

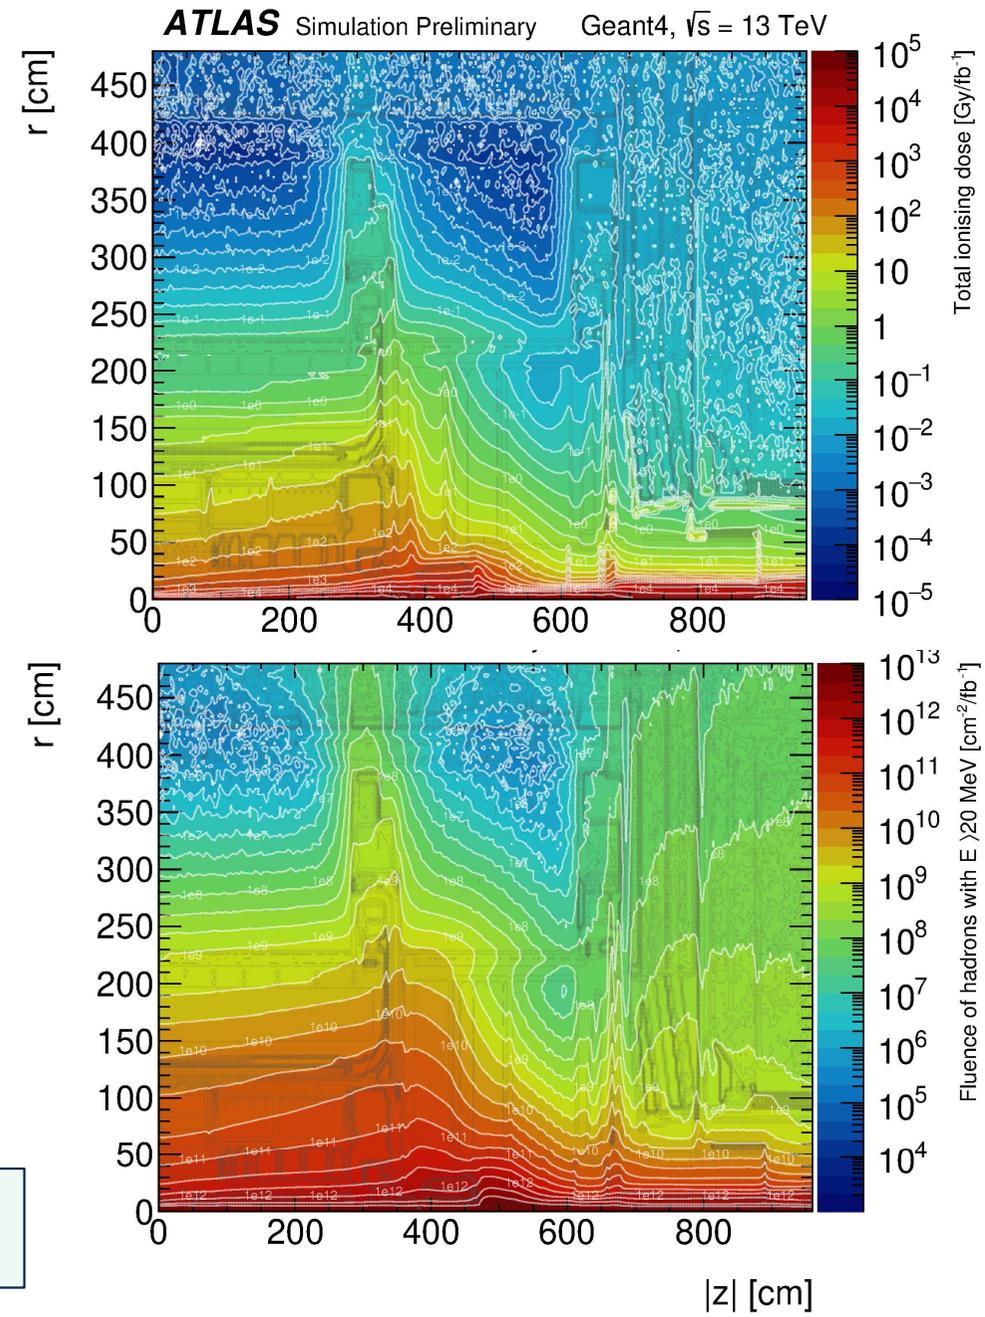

- Total pp cross section: 80 mb
  - For  $1 \times 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$ ,  $10^9$  events/s
  - With 25 ns collision rate: 25 events/collision
- Can be mitigated by Luminosity Levelling (already used at ALICE and LHCb IP)

# Luminosity: radiation effect

- Radiation effects from the high interaction rate:
  - high particle flux:
    - requirements on detector granularity
    - background rates and space charge effects
  - permanent damage on detector and electronics
  - detector activation

reproduced from B. Todd and S. Uznanski, *Radiation Risks and Mitigation in Electronics System*, in CERN-2015-003

- In the following I'll try to review:
  - general detector concepts in high-energy particle physics
  - which technologies have been chosen for the ATLAS and CMS detectors to cope with the LHC harsh environment
  - how they have been evolved to match the 10 more challenging environment at the LHC
- **Layout**
  - **ATLAS and CMS detector concepts**
  - **The detectors inside-out:**
    - **Inner tracking**
    - **Calorimetry**
    - **Muon systems**
  - **DAQ and trigger** (if time allows)
- Most material is from the experiment Phase II upgrade TDRs
  - sometimes not up-to-date, but it present the projects in an organic way
  - but I'll try to throw in some basic principles for non-experts

**I am not an expert on everything, my apologies for any incomplete/erroneous information reported**

# ATLAS AND CMS DETECTOR CONCEPTS

Istituto Nazionale di Fisica Nucleare

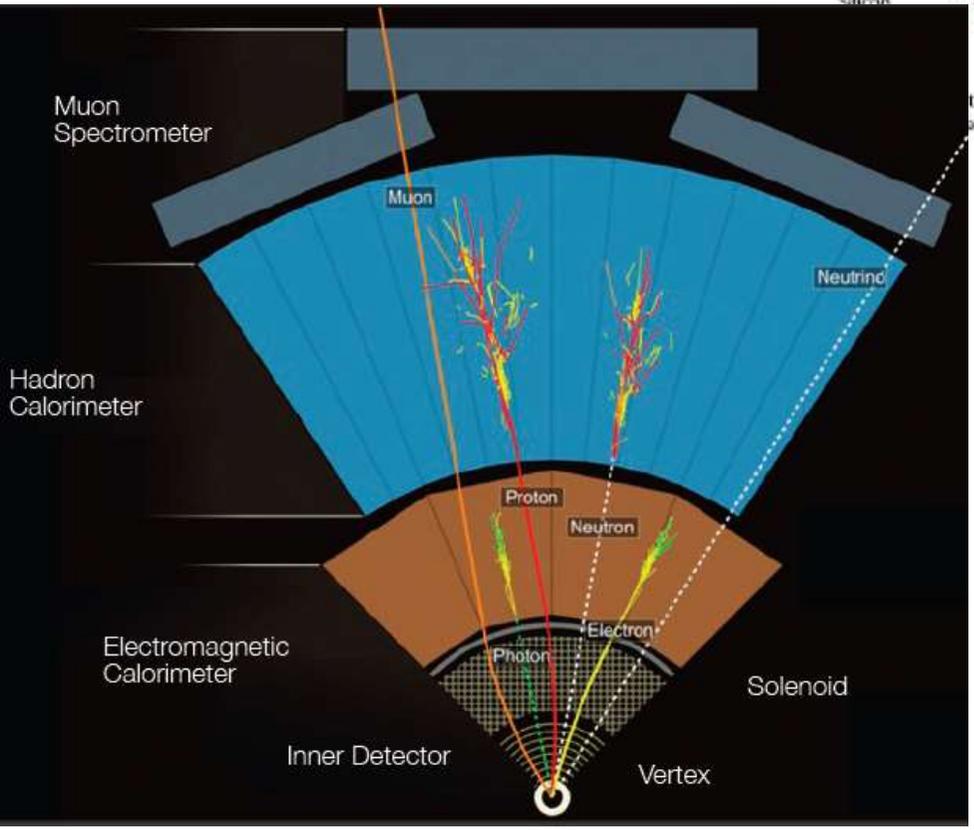

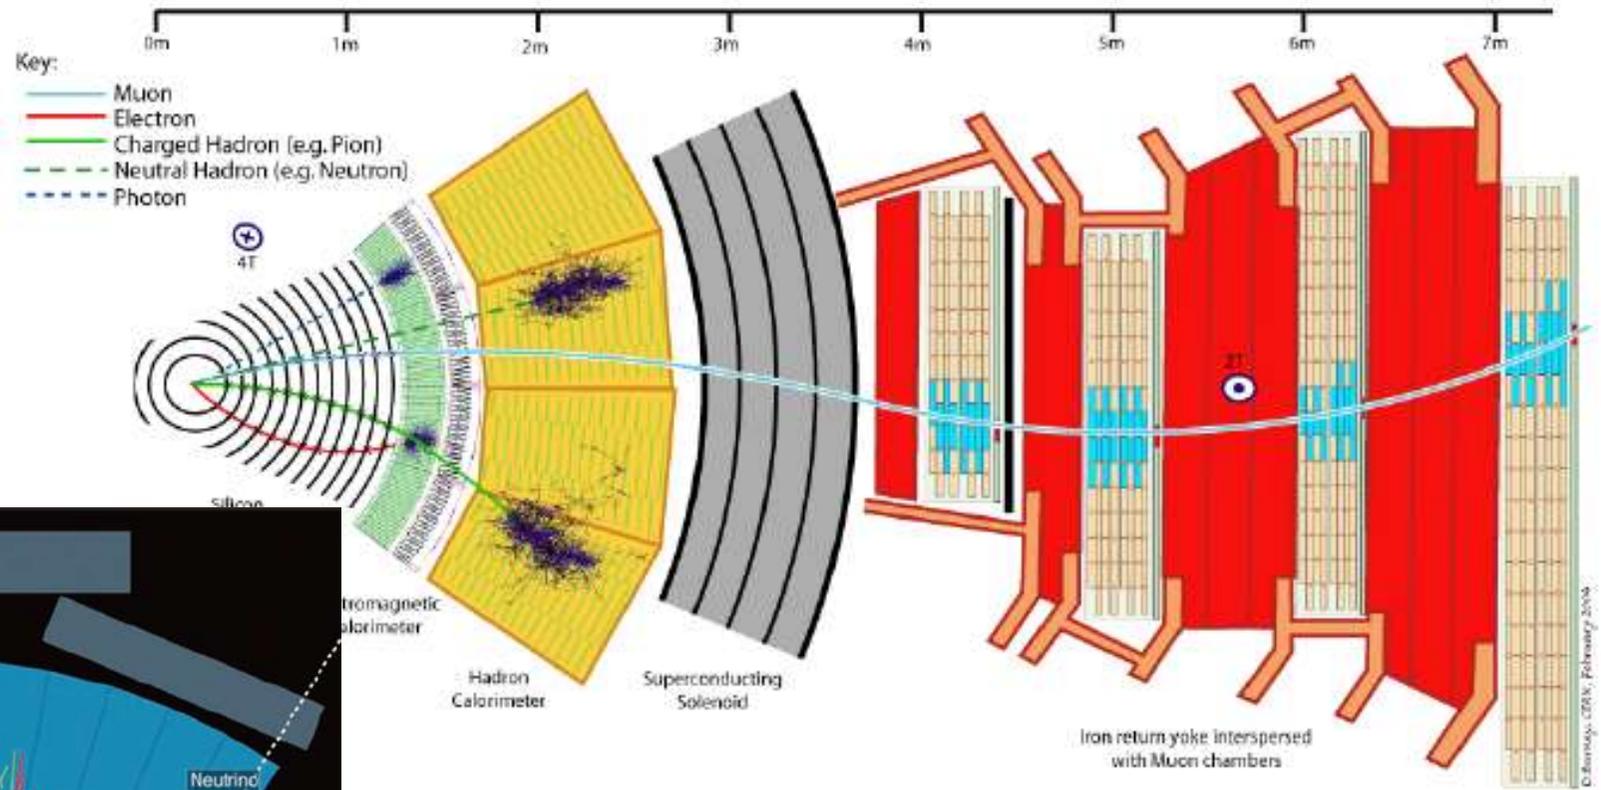

**Sezione di Milano**

**UNIVERSITÀ DEGLI STUDI DI MILANO**  
DIPARTIMENTO DI FISICA

# The "All-purpose" HEP Detector

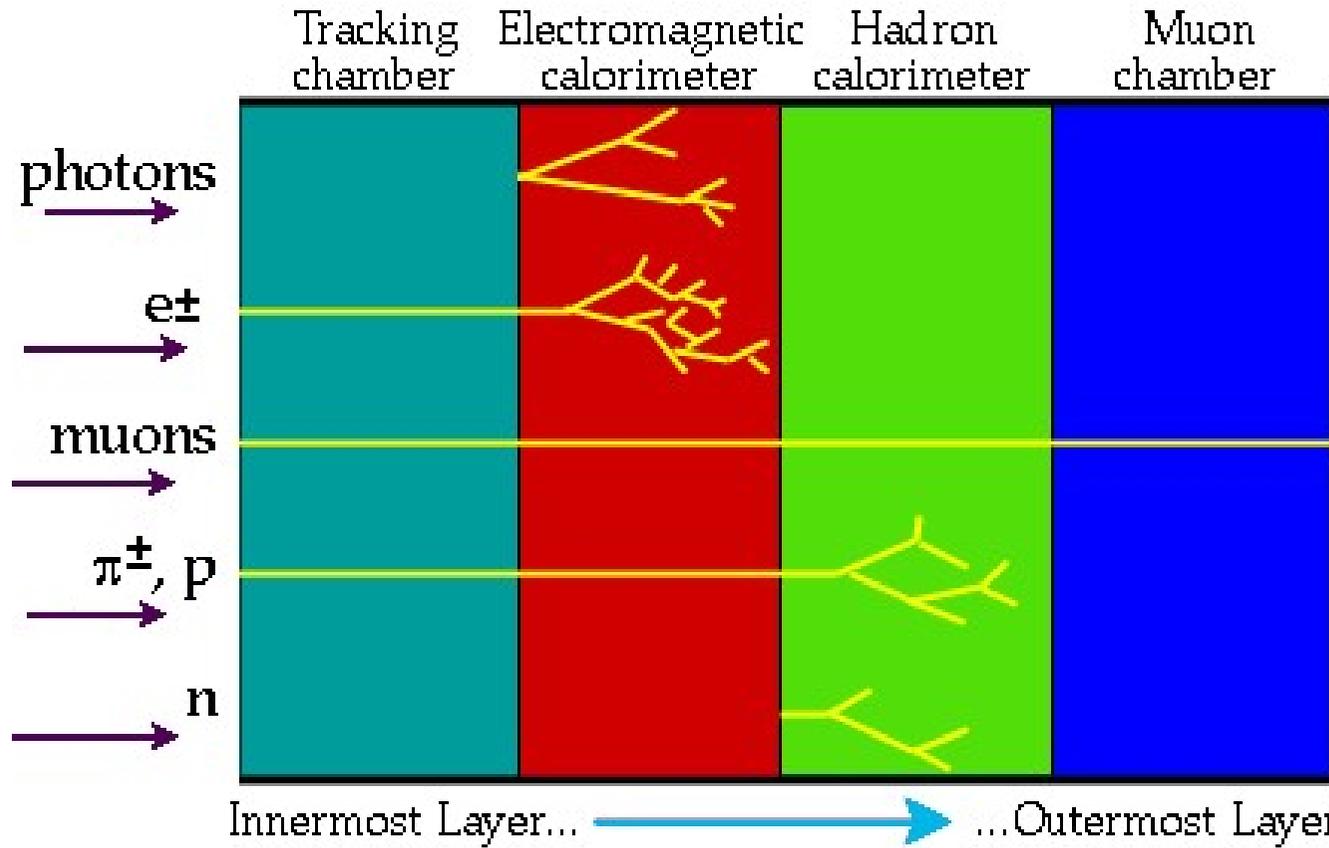

## CMS Slice

What's the difference?

## ATLAS Slice

# The "All-purpose" HEP Detector

**Momentum measurement  
decay vertex reconstruction,  
hadron identification  
Low material ( $\sim 1X_0$ )**

**Electron  
identification,  
photon detection  
 $\sim 20X_0, 1-2\lambda_I$**

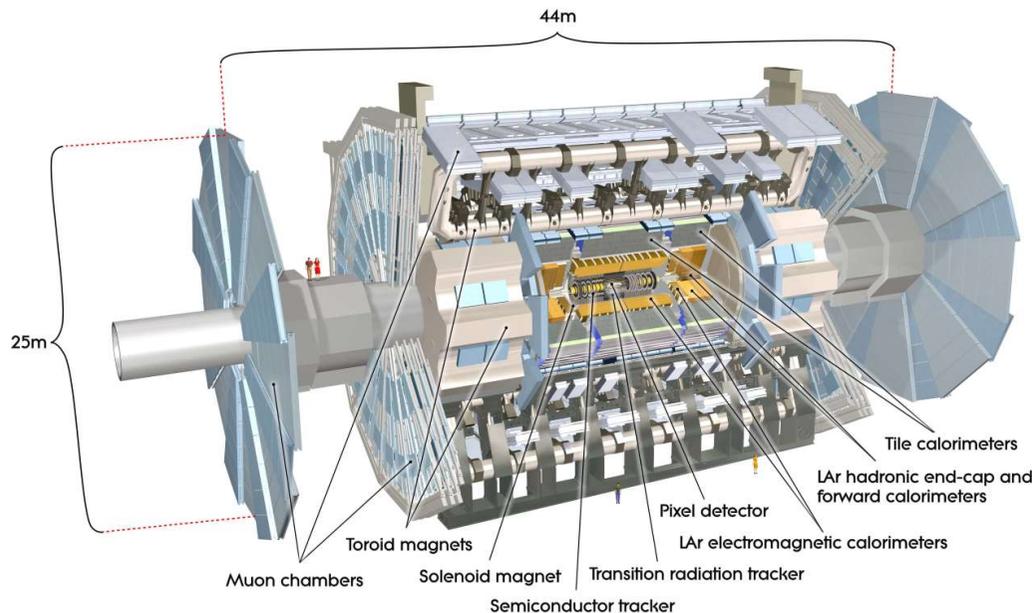

**Charged hadron  
absorption,  
neutral hadron  
detection  
 $5-6\lambda_I$**

**Identification of muons with  
enough energy to cross the  
calorimeters ( $>2-3$  GeV)**

## ATLAS

### A **Toroidal** LHC Apparatus

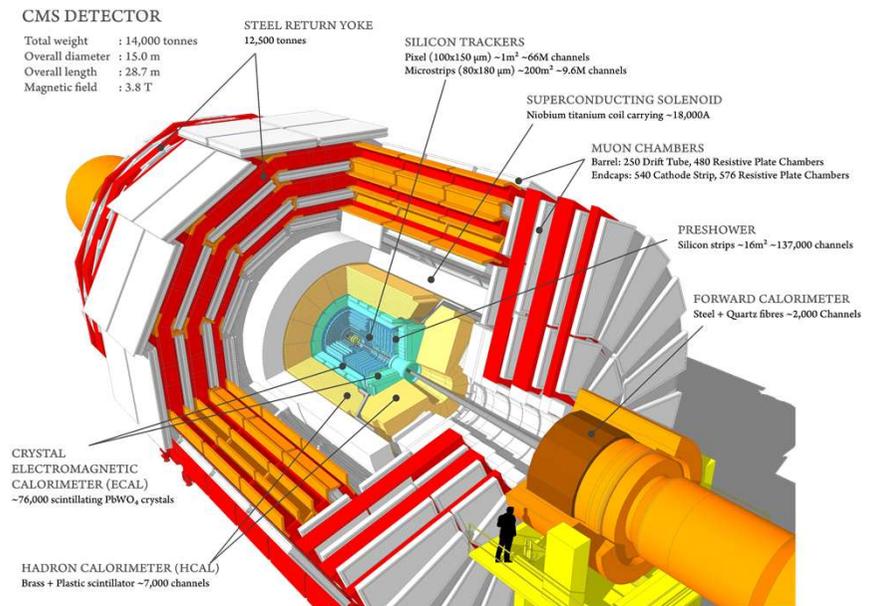

- Large air-core **toroids** integrated with the muon system
- Thin solenoid around the central tracker
  - **2 T** magnetic field
  - **inside** the calorimeters

## CMS

### Compact Muon **Solenoid**

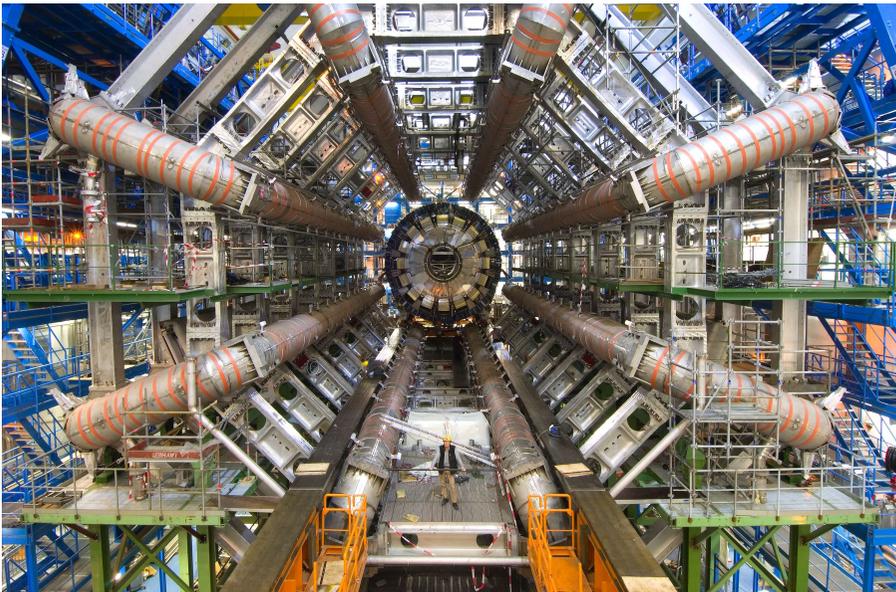

- Powerful solenoid
  - **4 T** magnetic field
  - **outside** of the calorimeter
- Muon system integrated in the solenoid **yoke**

## ATLAS

### A **Toroidal** LHC Apparatus

- Large air-core **toroids** integrated with the muon system
- Thin solenoid around the central tracker
  - **2 T** magnetic field
  - **inside** the calorimeters

## CMS

### Compact Muon **Solenoid**

- Powerful solenoid
  - **4 T** magnetic field
  - **outside** of the calorimeter
- Muon system integrated in the solenoid **yoke**

- A charged particle bending radius in magnetic field:

$$p[\text{GeV}/c] = 0.3 q B[\text{T}] R[\text{m}]$$

- Deflection due to the Lorenz force on a length  $L$ :

$$\theta = \frac{L}{R} = \frac{0.3 qBL}{p}$$

- in case of non-uniform magnetic field, use the bending power

$$\int Bdl$$

- Deflection measurement

- direction before and after the bending field

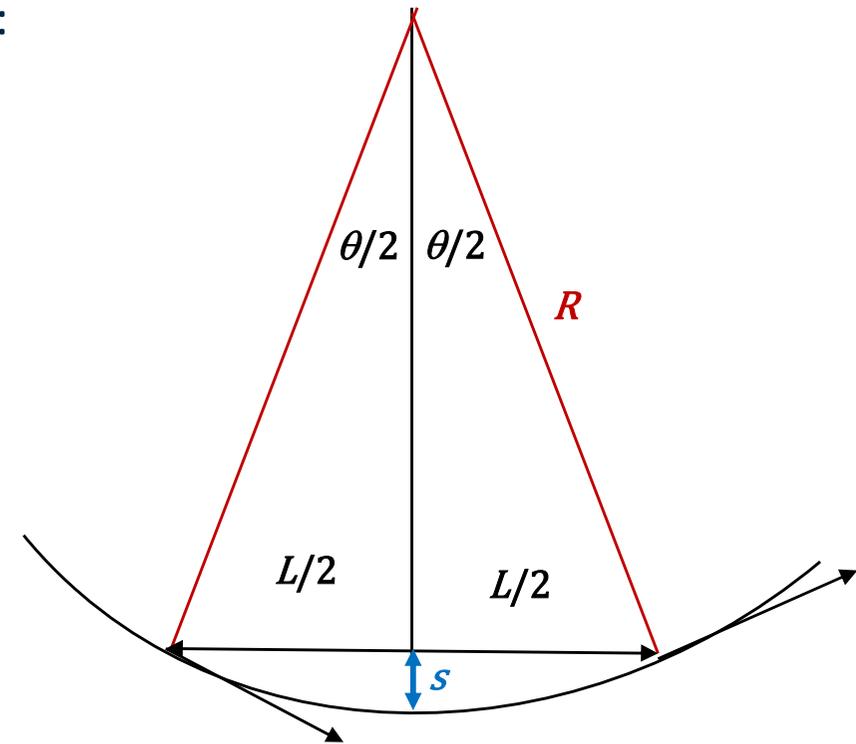

$$\frac{\sigma_p}{p} = \frac{\sigma_\theta}{\theta} = \frac{p\sigma_\theta}{0.3 qBL}$$

- Sagitta measurement

- deviation from a "straight line" inside the magnetic field:

$$s = R(1 - \cos \theta) \approx \frac{L^2}{8R} = \frac{0.3 qBL^2}{8p}$$

$$\frac{\sigma_p}{p} = \frac{\sigma_s}{s} = \frac{8p\sigma_s}{0.3 qBL^2}$$

Detector resolution:

$$\frac{\sigma_p}{p} \propto p$$

- Deflection of a charged particle trajectory due to soft interactions with the material

- on average  $\langle \varepsilon_p \rangle = 0$ ,  $\langle \theta_p \rangle = 0$
- but the standard deviation is finite:

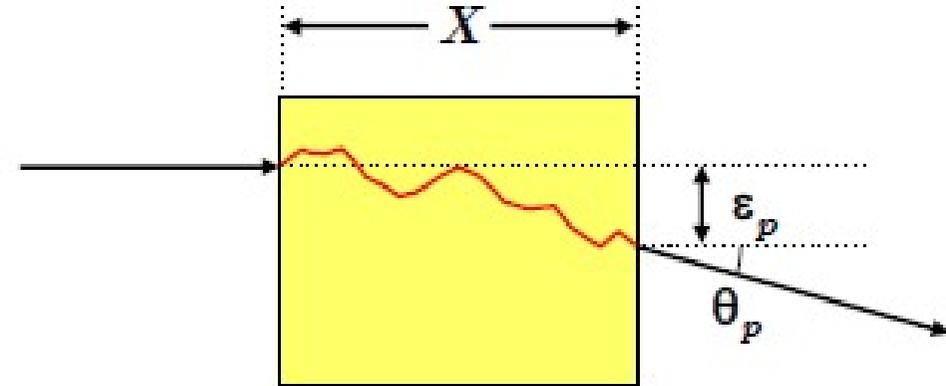

$$\theta_{p,rms} = \frac{13.6 \text{ MeV}}{\beta c p} z \sqrt{\frac{X}{X_0}} \left( 1 + 0.038 \ln \frac{X}{X_0} \right)$$

- $\beta c$  particle velocity
- $p$  particle momentum
- $z$  particle charge (in units of  $e$ )
- $X_0$  is the radiation length of the material

$$X_0 \approx \frac{716.4 \text{ g cm}^{-2} A}{Z(Z+1) \ln(287/\sqrt{Z})} \times \frac{1}{\rho}$$

- $A, Z$  mass and atomic number of the element
- $\rho$  density

Relevant for small thickness

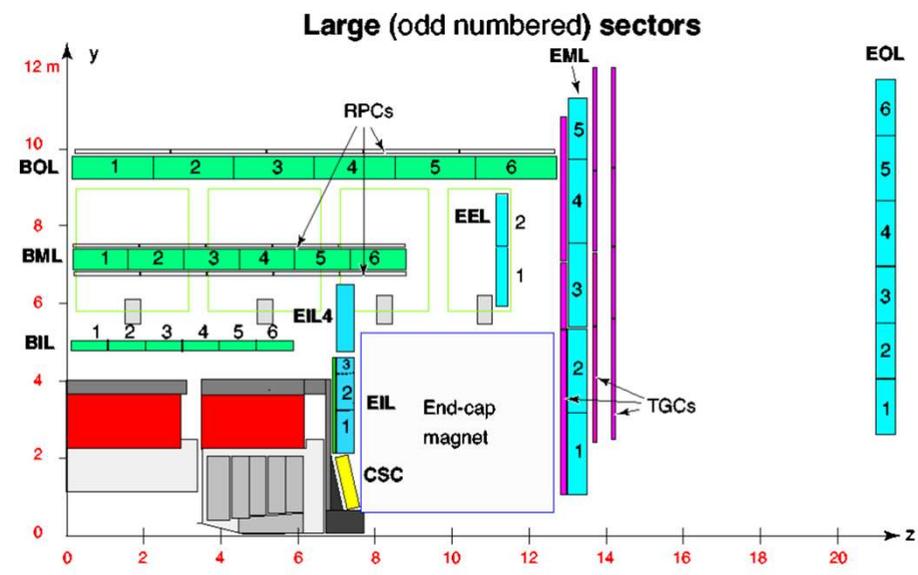

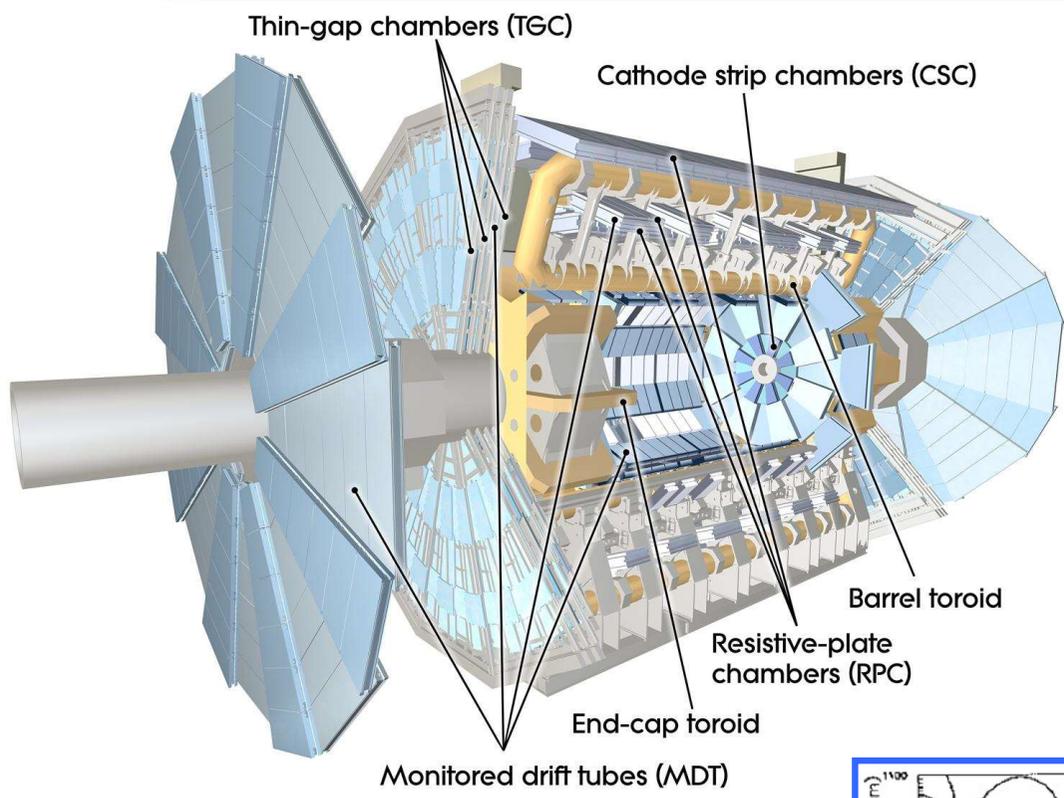

- Full covariance matrix is given by

$$\varepsilon_{p,rms} = \frac{1}{\sqrt{3}} \theta_{p,rms} X$$

$$\langle \varepsilon_p \theta_p \rangle = \frac{1}{2} \theta_{p,rms}^2 X$$

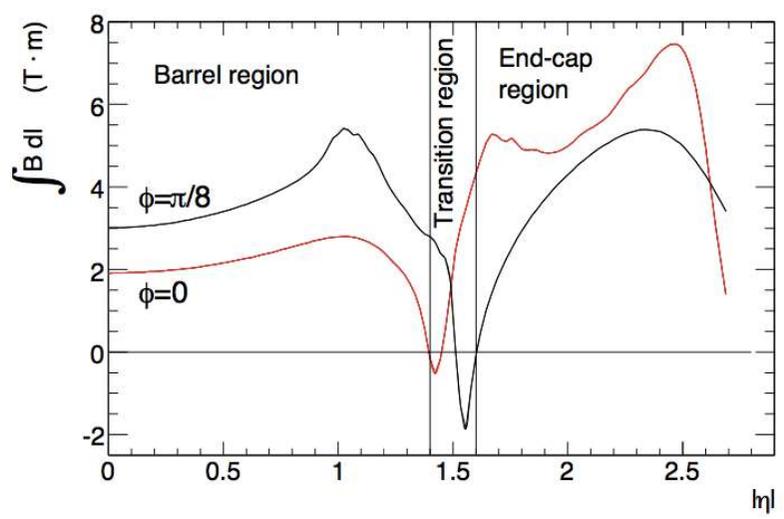

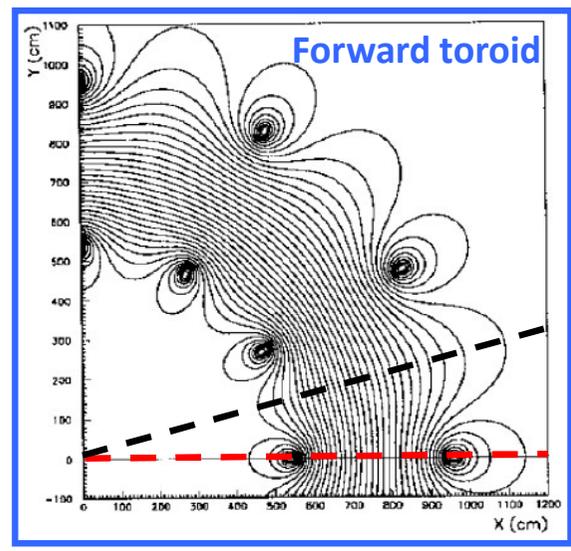

Resolution term due to multiple scattering:

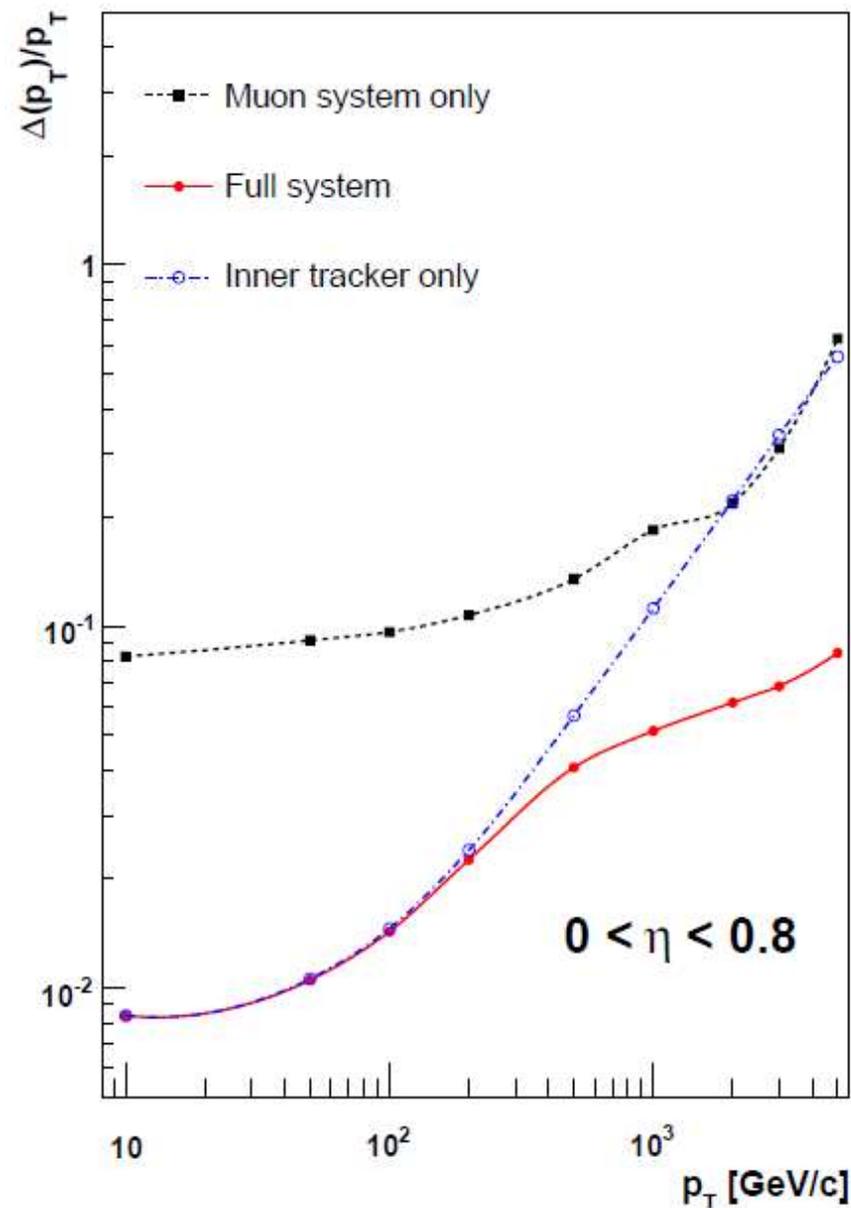

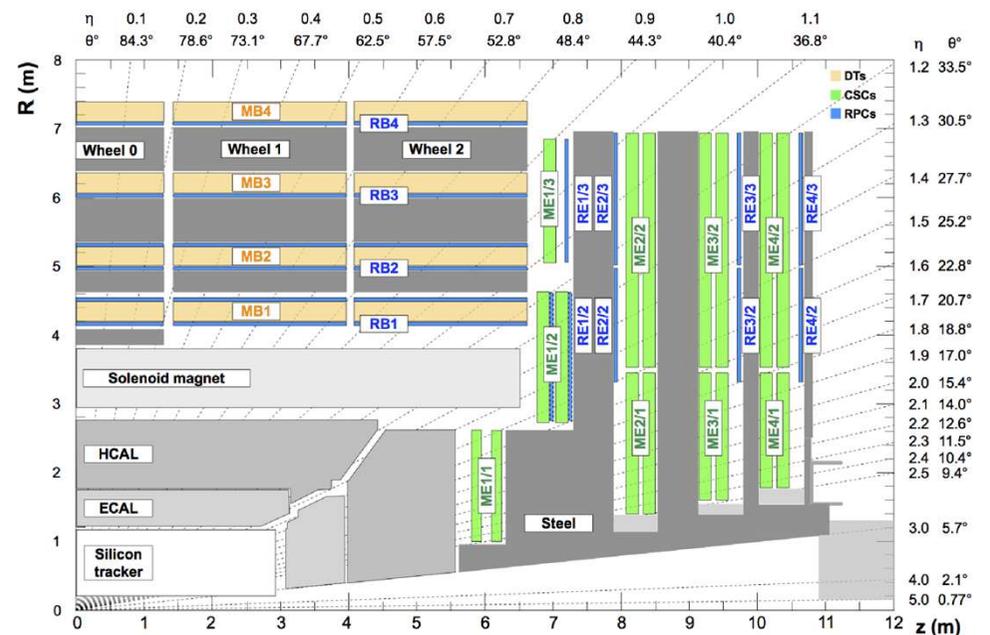

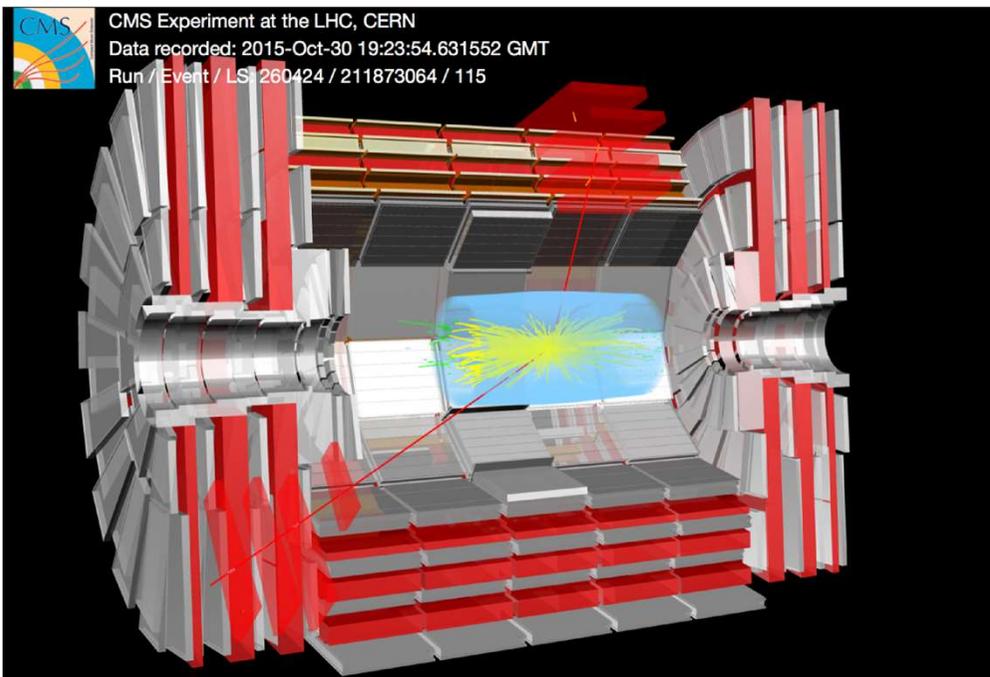

$$\frac{\sigma_p}{p} = \frac{\theta_{p,rms}}{\theta} \propto \frac{1/p}{1/p} \propto \text{const.}$$

## Instrumented air-core toroid system:

- bending power 1–7.5 Tm
- standalone momentum reconstruction capability  $\sigma_{p_T}/p_T = 10\%$  at  $p_T=1$  TeV

- **Pixel Detector**

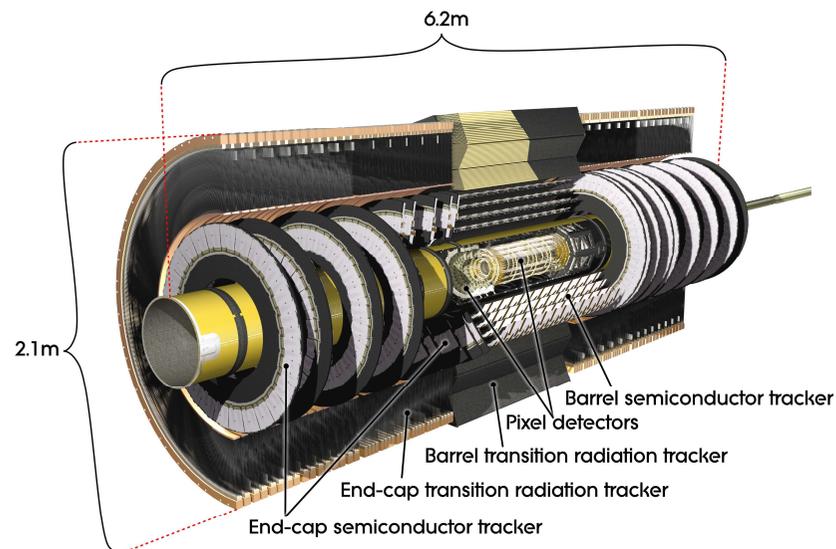

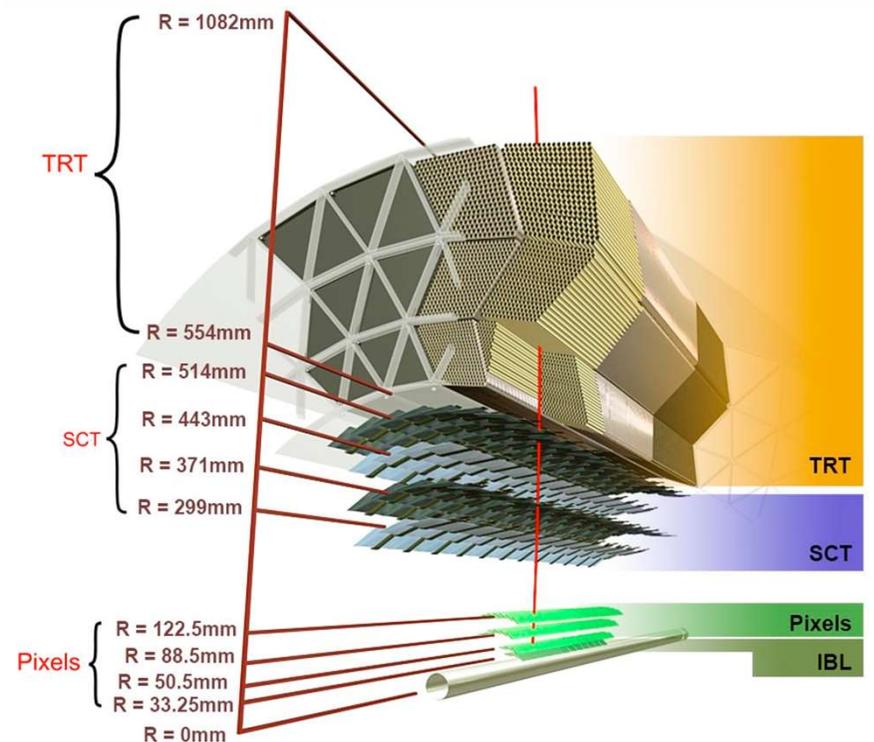

- 4 barrel layers, 3+3 disks,  **$10^8$  pixels**
- barrel radii: 33, 50, 85, 122 mm
- pixel size  $50 \times 400 \mu\text{m}^2$  (50x250 IBL)
- $\sigma_{R\Phi} = 6\text{-}10 \mu\text{m}$ ,  $\sigma_z \sim 66 \mu\text{m}$

- **SemiConductor Tracker**

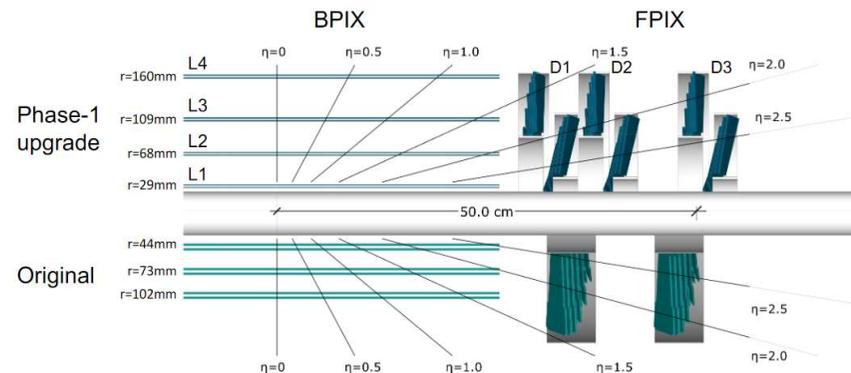

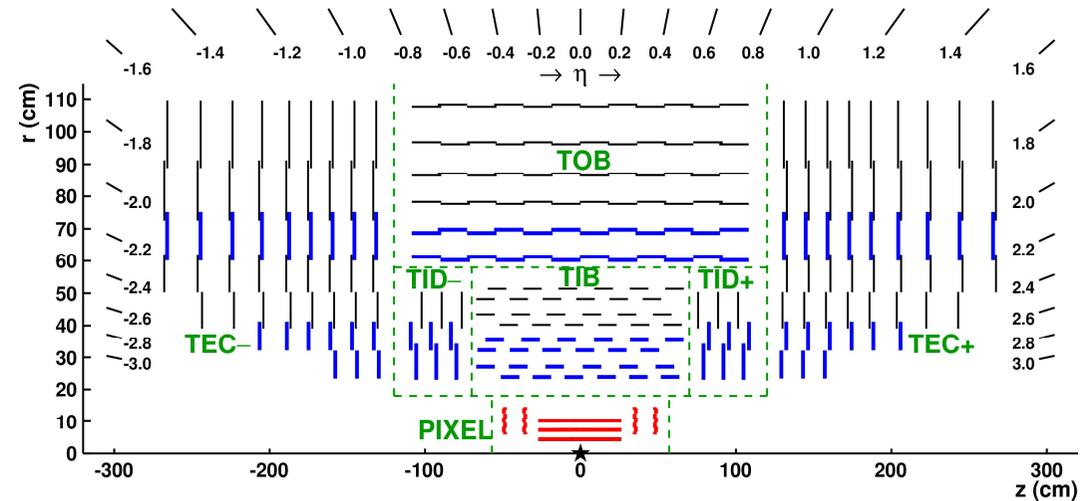

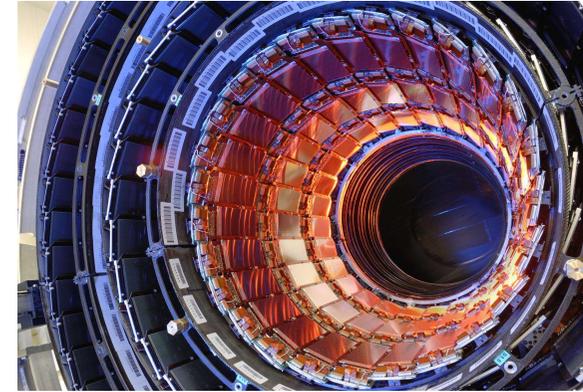

- 4 barrel layers, 7+7 disks,  **$6 \times 10^6$  strips**
- barrel radii: 30, 37, 44, 51 cm
- strip pitch  $80 \mu\text{m}$  (40 mrad stereo)
- $\sigma_{R\Phi} = 16 \mu\text{m}$ ,  $\sigma_z = 580 \mu\text{m}$

- **Transition Radiation Tracker**

- barrel  $55 < R < 102$  cm
- 36 layers,  **$4 \times 10^5$  drift tubes**
- 4 mm diameter
- $\sigma_{R\Phi} = 170 \mu\text{m}$
- Also contributes to electron identification

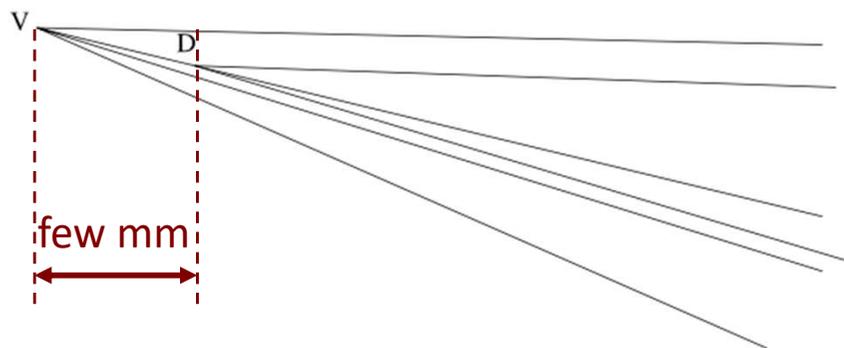

- **Pixel Detector**
  - 3 barrel layers, 2+2 disks,  **$10^7$  pixels**
  - barrel radii: 44, 73, 102 mm
  - upgraded to 4 barrel layers, 3+3 disks,  **$10^8$  pixels**
  - pixel size  $100 \times 150 \mu\text{m}^2$
  - $\sigma_{R\Phi} \sim 10 \mu\text{m}$ ,  $\sigma_z \sim 10 \mu\text{m}$
- **Internal Silicon Strip Tracker (TIB, TID)**
  - 4 barrel layers, 3+3 disks,  **$2 \times 10^6$  strips**
  - barrel radii: 20-55 cm
  - strip pitch 80-120  $\mu\text{m}$
  - $\sigma_{R\Phi} \sim 23-35 \mu\text{m}$
- **External Silicon Strip Tracker (TOB, TEC)**
  - 6 barrel layers, 9+9 disks,  **$7 \times 10^6$  strips**
  - barrel radii: max 116 cm
  - strip pitch 120-180  $\mu\text{m}$
  - $\sigma_{R\Phi} \sim 35-53 \mu\text{m}$

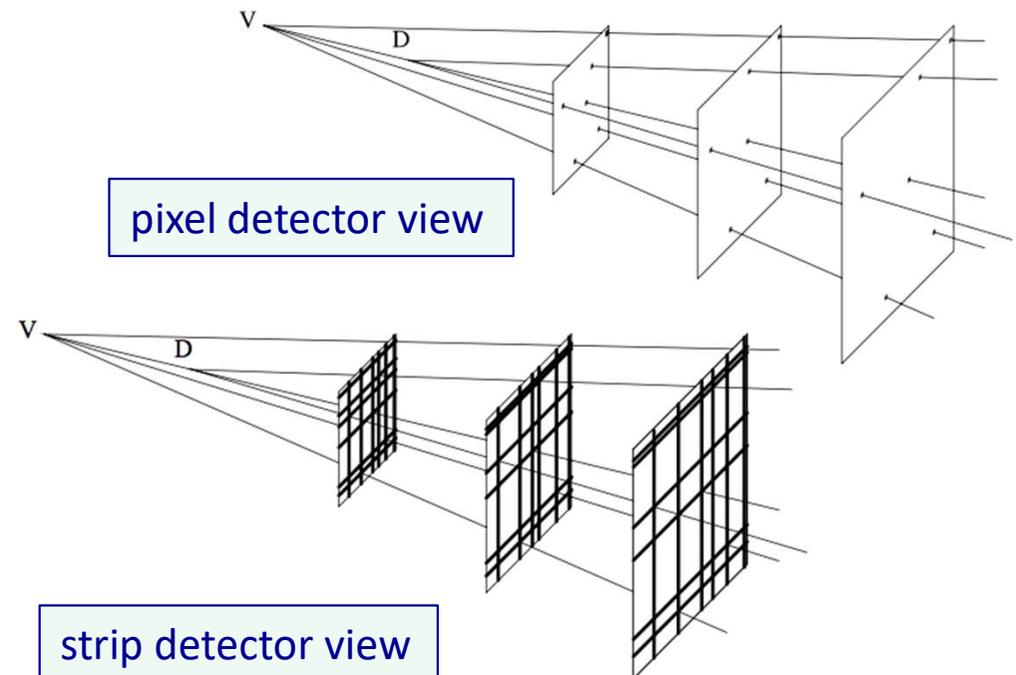

- The inner tracking system purpose is to:
  - measure particle momentum
  - identify and separate the pileup interactions
  - detect decay of particles with a flight length from 1 mm ( $b$ -,  $c$ -hadrons,  $\tau$ ) to several cm ( $s$ -hadrons, new physics)
- and has to cope with:
  - particle rate: 100 MHz/cm<sup>2</sup> at  $1 \times 10^{34}$  cm<sup>-2</sup>s<sup>-1</sup>
  - doses up to  $10^7$  Gy and NIEL  $10^{16}$  (1 MeV  $n_{eq}$ /cm<sup>-2</sup>)

few  $\mu$ m  
resolution

several particles/cm<sup>2</sup>/bunch crossing

opening angle  $\sim 0.1$  rad  
transverse vertex resolution  $\sim 10$   $\mu$ m  
decay length resolution  $\sim 100$   $\mu$ m

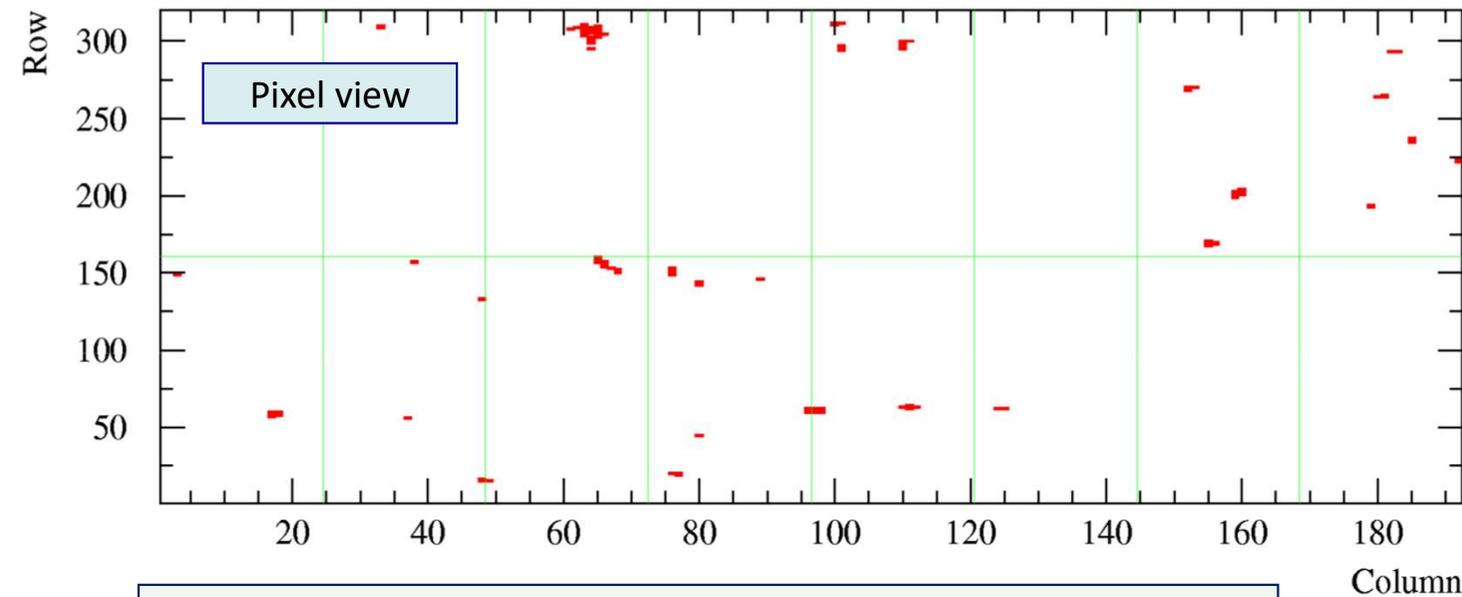

pixel detector view

strip detector view

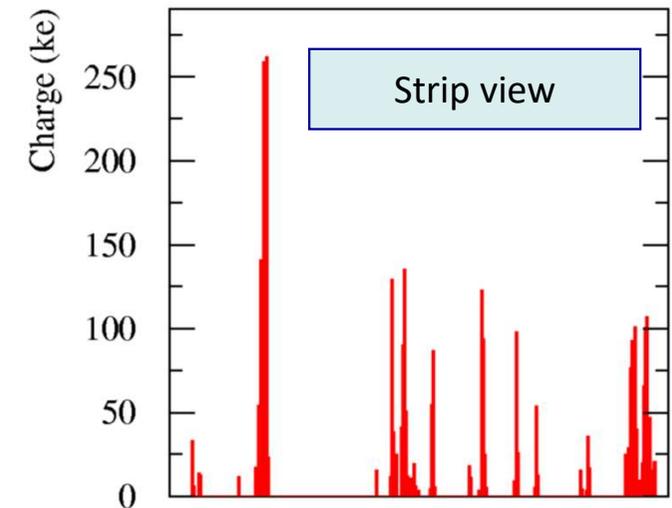

- The inner tracking system purpose is to:
  - measure particle momentum
  - identify and separate the pileup interactions
  - detect decay of particles with a flight length from 1 mm ( $b$ -,  $c$ -hadrons,  $\tau$ ) to several cm ( $s$ -hadrons, new physics)
- and has to cope with:
  - particle rate: 100 MHz/cm<sup>2</sup> at  $1 \times 10^{34}$  cm<sup>-2</sup>s<sup>-1</sup>
  - doses up to  $10^7$  Gy and NIEL  $10^{16}$  (1 MeV  $n_{eq}$ /cm<sup>-2</sup>)

few  $\mu$ m  
resolution

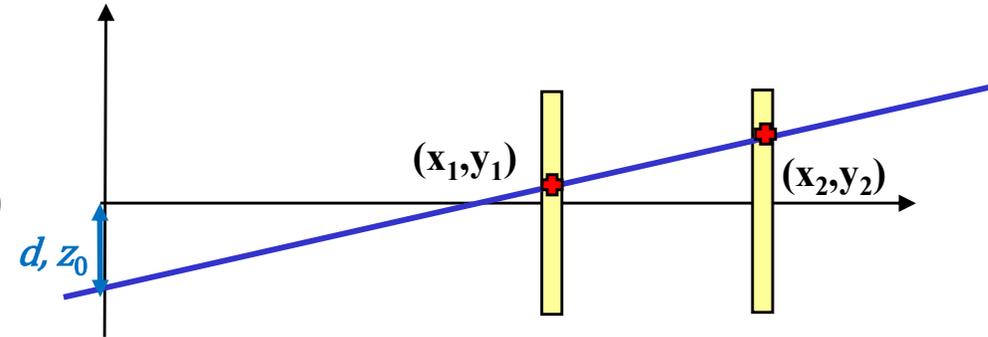

several particles/cm<sup>2</sup>/bunch crossing

Simulated event in the ATLAS pixel at  $R=50$  mm and  $10^{34}$  cm<sup>-2</sup>s<sup>-1</sup>

- $d$  transverse distance with of trajectory from the interaction region
  - $\sim 0$  for primary particles
  - $\sim c\tau$  for decay products (independent of boost)
- $z_0$  position along the beam axis
- Resolution is dominated by the first measurement points
  - rest of trajectory determine the curvature/momentum

- **Detector resolution**

$$\sigma_d = \sqrt{\frac{n^2 + 1}{(n - 1)^2} \sigma_y}$$

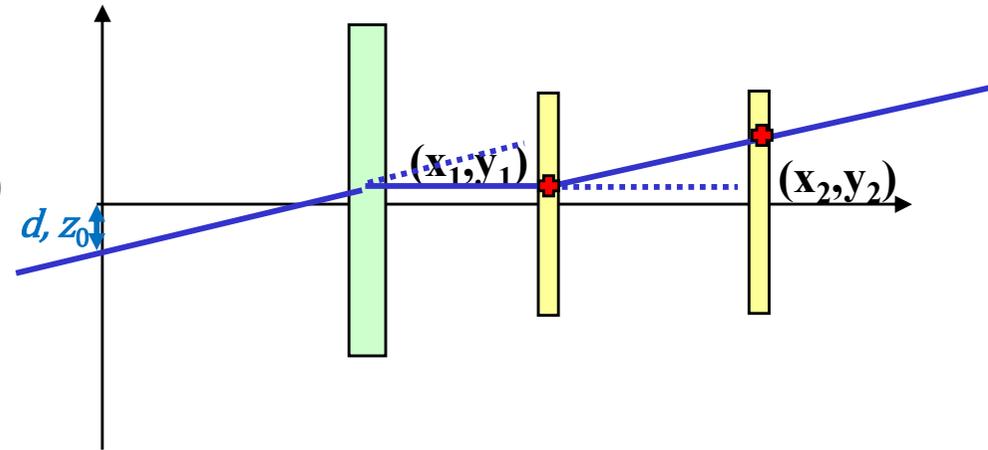

- $n = x_2/x_1$  often referred as lever arm

- **Multiple scattering**

$$\sigma_d = \sqrt{\sum_i x_i^2 \theta_{p,rms,i}^2}$$

- where the index  $i$  runs over all material crossed by the particle up to and including the first measured point

- $d$  transverse distance with of trajectory from the interaction region
  - $\sim 0$  for primary particles
  - $\sim c\tau$  for decay products (independent of boost)
- $z_0$  position along the beam axis
- Resolution is dominated by the first measurement points
  - rest of trajectory determine the curvature/momentum

- **Detector resolution**

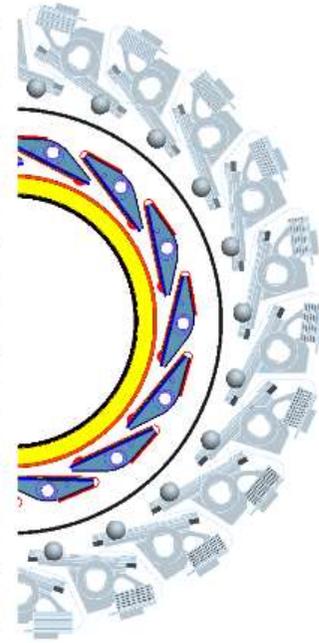

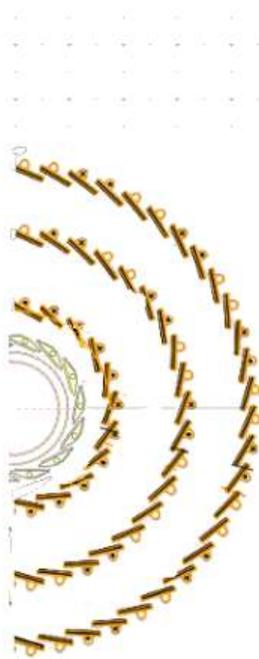

$$\sigma_d = \sqrt{\frac{n^2 + 1}{(n - 1)^2}} \sigma_y \propto \text{cost.}$$

- $n = x_2/x_1$  often referred as lever arm

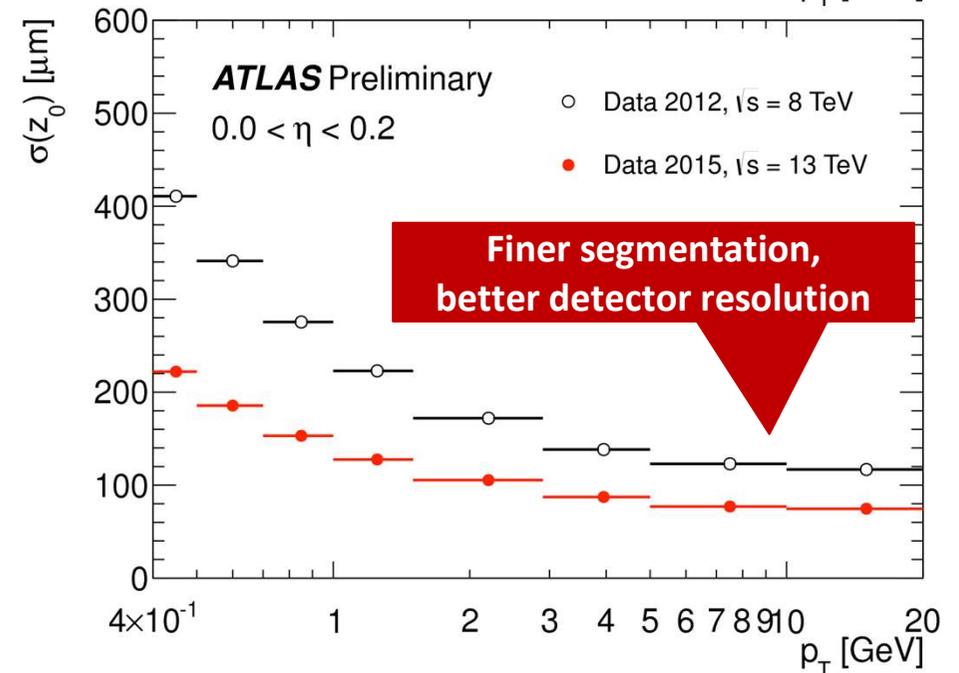

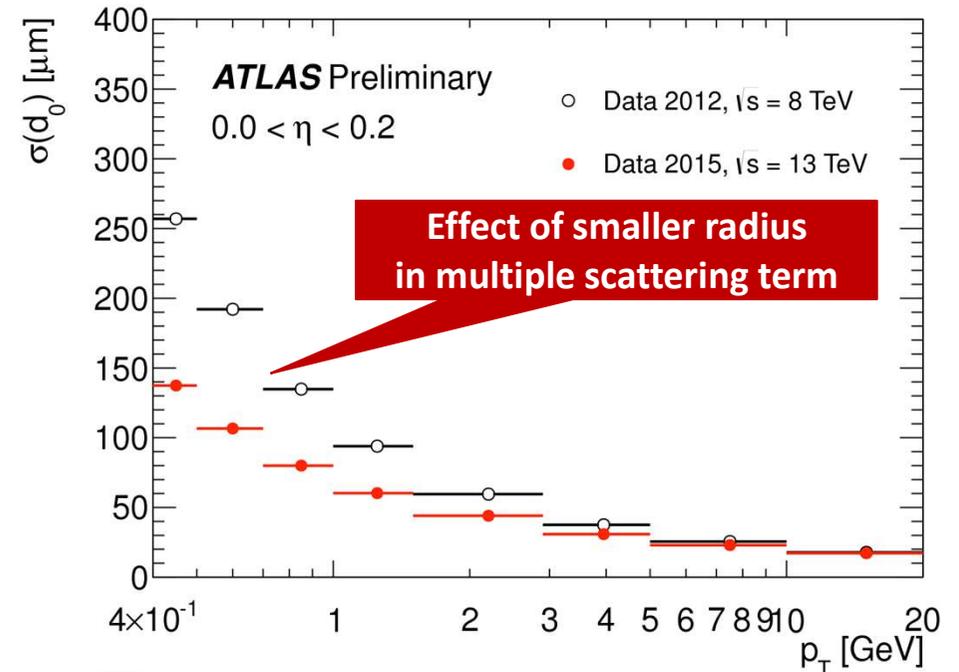

- **Multiple scattering**

$$\sigma_d = \sqrt{\sum_i x_i^2 \theta_{p,\text{rms},i}^2} \propto \frac{1}{p}$$

- where the index  $i$  runs over all material crossed by the particle up to and including the first measured point

- During Run1 (up to 2012), innermost barrel layer:
  - radius at 50 mm
  - pixel size  $50 \times 400 \mu\text{m}^2$
- In Run2, inserted a new layer
  - radius at 33 mm
  - pixel size  $50 \times 250 \mu\text{m}^2$

# Back to history: most famous $t\bar{t}$

## $e + 4 \text{ jet event}$

40758\_44414

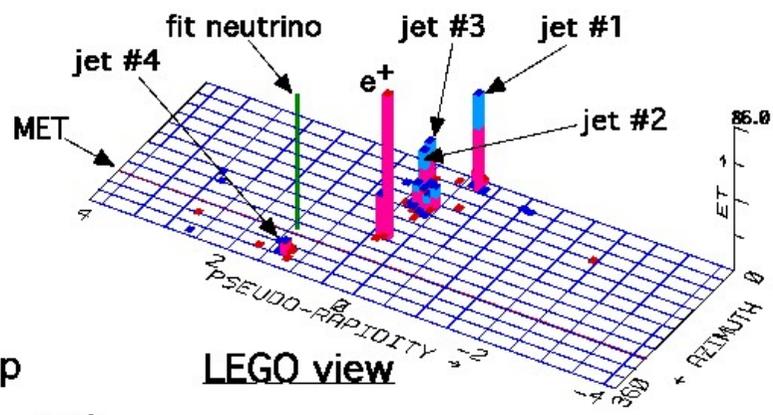

24-September, 1992

TWO jets tagged by SVX

fit top mass is  $170 \pm 10 \text{ GeV}$

$e^+$ , Missing  $E_t$ , jet #4 from top

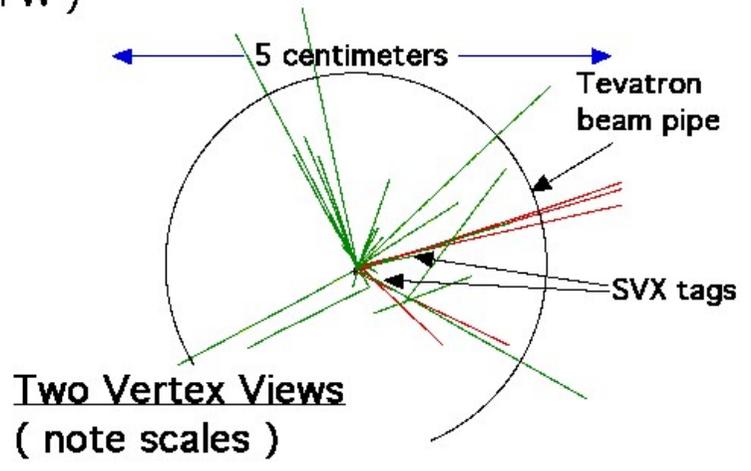

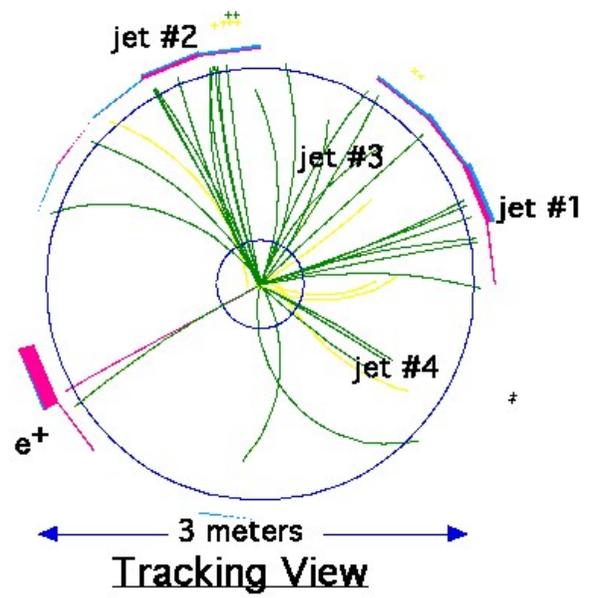

jets 1,2,3 from top ( 2&3 from W )

$$p\bar{p} \rightarrow t\bar{t} + X$$

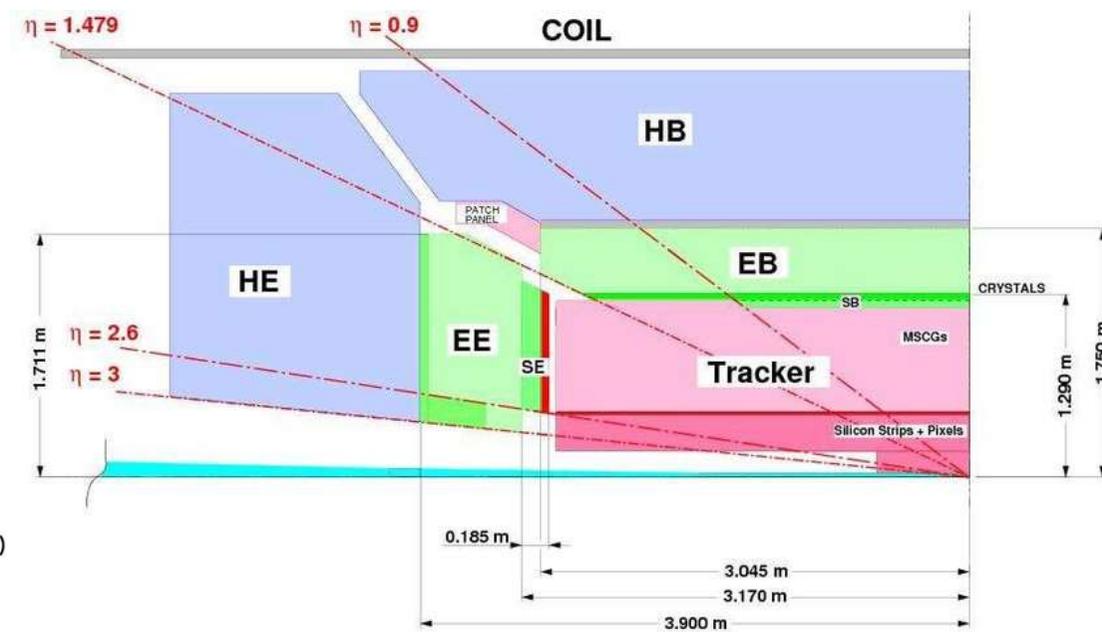

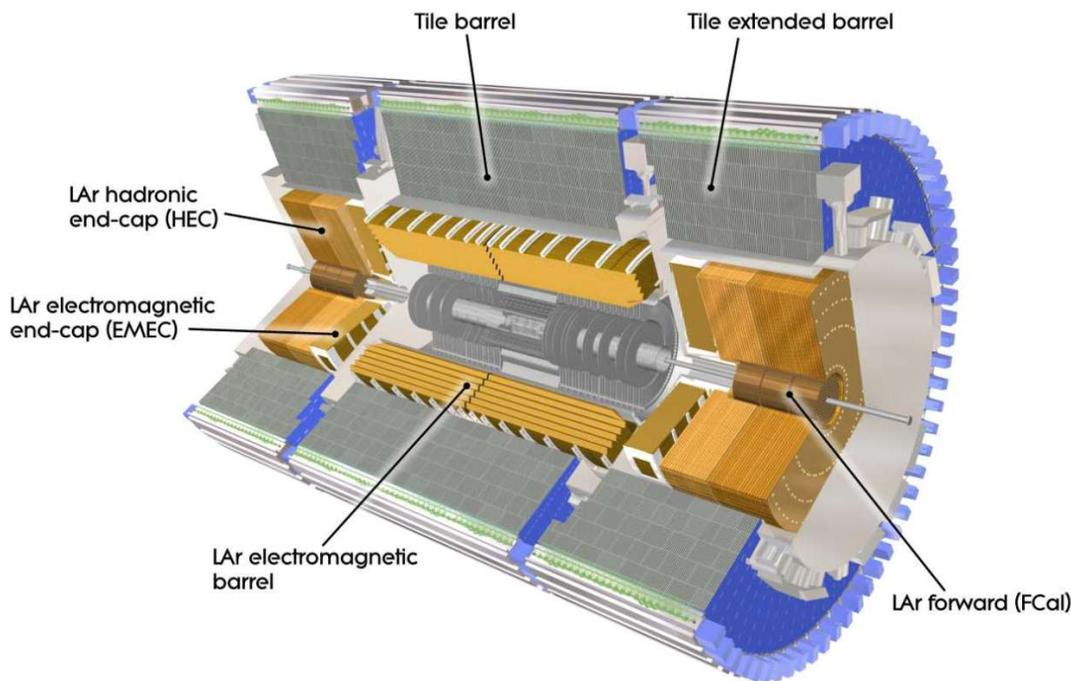

$$\downarrow \bar{b}W^- \rightarrow \bar{b}q\bar{q}$$

$$\downarrow bW^+ \rightarrow be^+\nu_e$$

- Lorentz boost increases decay length  $L$
- it decreases opening angle of decay products to build the vertex, increasing  $\sigma_L$
- The two effects compensate
 
$$\frac{\sigma_L}{L} = O\left(\frac{\sigma_d}{c\tau}\right)$$
  - $\tau$  average lifetime of decaying particle

- Detection of neutral particles
  - interaction and conversion to charged particle
  - energy deposited by ionization
- Lepton identification
- Energy measurement (improving with increasing energy)
- Neutrino/Dark particle detection (missing energy/momentum)

High energy particles have different interactions with matter:

- **electrons and photons** degrade their energy by bremsstrahlung and pair production; the length scale is given by the *radiation length*  $X_0$ :

$$X_0 \approx \frac{716.4 \text{ g cm}^{-2} A}{Z(Z+1) \ln(287 / \sqrt{Z})}$$

- **hadrons** undergo nuclear interactions, with mean free path given by the *interaction length*  $\lambda_I$ :

$$\lambda_I \approx 35 \text{ g cm}^{-2} A^{1/3}$$

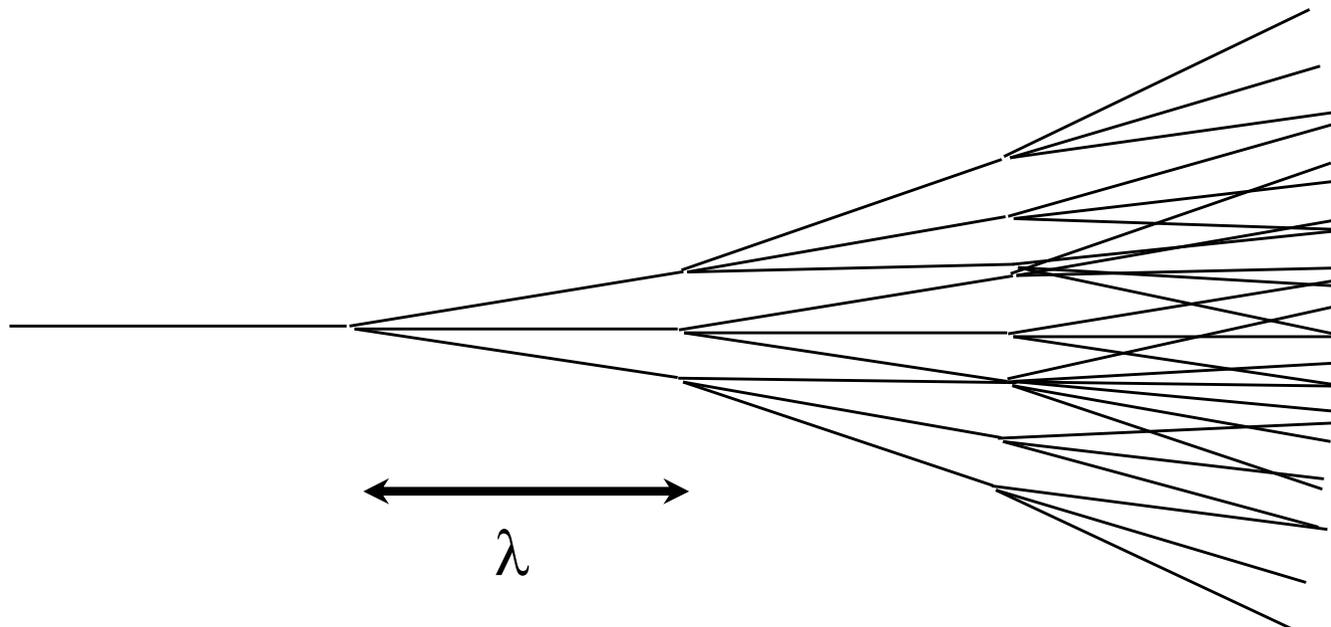

- as to **muons**, and **low energy charged particles**, usually the dominant energy loss process is by soft collisions following the Bethe-Bloch law:

$$\frac{dE}{dx} = \frac{N_A}{\varepsilon_0} z^2 e^2 \frac{Z}{A} \frac{1}{\beta^2} \left[ \frac{1}{2} \ln \frac{2m_e c^2 \beta^2 \gamma^2 T_{\max}}{I^2} - \beta^2 - \frac{\delta}{2} \right]$$

which is in the interval 1-2 MeV/ g cm<sup>-2</sup> for most materials.

Despite electrons and hadrons having different behavior, it is possible to grasp the more relevant features through a simplified model:

- a particle fly a fixed length  $\lambda$  between two interactions;
- at each interaction  $m$  particles are produced, with typical transverse momentum  $p_T$ ;
- the secondary particles interact again, originating a particle shower, until they fall below a critical energy  $E_c$ ;
- after that they are absorbed in a typical length given by  $E_c/(-dE/dx)$ .

Starting with a primary particle of energy  $E$ :

- the total number  $N$  of secondary particles is

$$N = E / E_c$$

- this number is reached at a length  $n\lambda$ , where  $n$  is given by:

$$N = m^n \Rightarrow n = \ln \frac{E}{E_c} / \ln m$$

resulting in shower length  $L$ :  $L = \frac{\lambda}{\ln m} \ln \frac{E}{E_c} + \frac{E_c}{-dE/dx}$

Longitudinal dimension  
scales logarithmically on  $E$

- between the  $i^{\text{th}}$  and the  $(i+1)^{\text{th}}$  interactions, the secondaries expand by  $R_i = \lambda \frac{p_T}{E_i} = \frac{\lambda p_T}{E} m^i$  resulting in a transverse shower size at maximum,  $R_{\text{max}}$ :

$$R_{\text{max}} = \sum_{i=1}^{n-1} \frac{\lambda p_T}{E} m^i = \frac{\lambda p_T}{E} \frac{m^n - m}{m-1} \approx \frac{1}{m-1} \frac{\lambda p_T}{E_c}$$

- finally shower fluctuations will be driven by the number of interactions:

$$\sigma \propto \sqrt{\frac{N}{m}} = \sqrt{\frac{E}{mE_c}}$$

$\sigma_E/E \propto 1/\sqrt{E}$

## Electromagnetic showers

- $m = 2$
- $\lambda = X_0$
- $p_T = \sqrt{\frac{4\pi}{\alpha}} m_e c$
- $E_c = \frac{800 \text{ MeV}}{Z+1.2}$

- Shower dimension

- longitudinal:  $L = \ln \frac{E}{E_c} + 14$
- trasversal:  $R = 2\rho_M, \rho_M = X_0 \frac{E_s}{E_c}$   
(Moliere radius)

- Energy resolution

- clearly technology dependent

$$\frac{\sigma_E}{E} = \frac{1 - 20\%}{\sqrt{E[\text{GeV}]}}$$

Compact ~ 10 cm  
High energy resolution

## Hadronic showers

- $m \sim 6$
- $\lambda = \lambda_I$
- $p_T = p_F \approx 340 \text{ MeV}/c$
- $E_c \approx 2m_\pi$

- Shower dimension

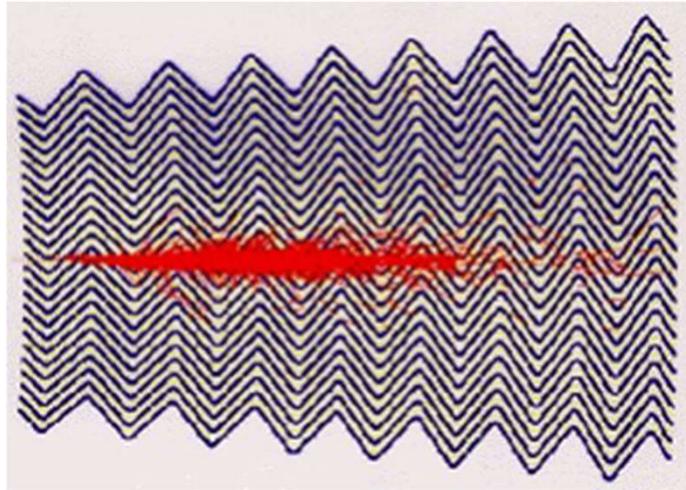

- longitudinal:  $L = 0.2 \ln E[\text{GeV}] + 3.2$
- trasversal:  $R = \lambda_I$

- Energy resolution

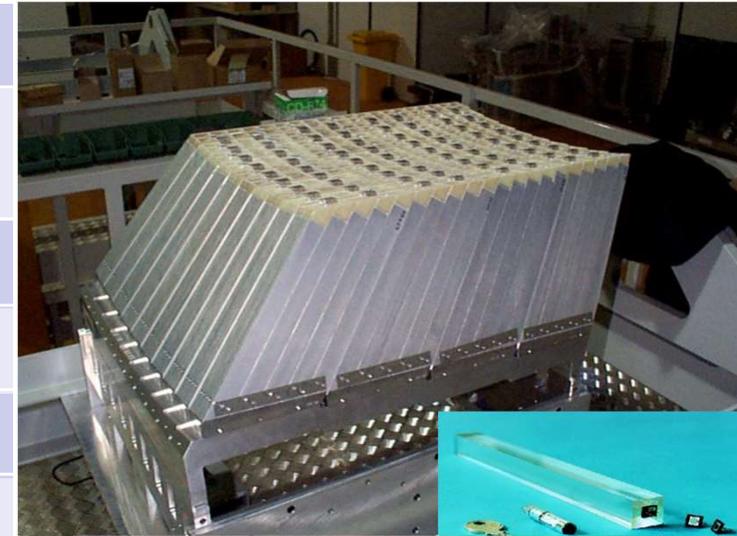

- clearly technology dependent

$$\frac{\sigma_E}{E} = \frac{50 - 100\%}{\sqrt{E[\text{GeV}]}}$$

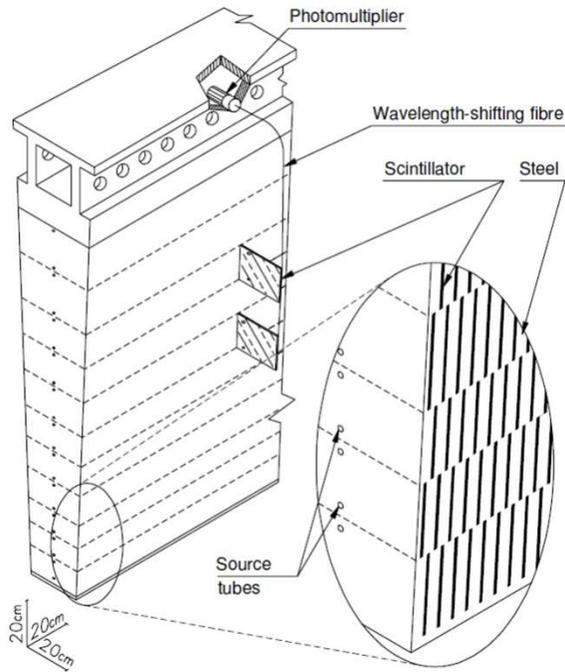

Some interaction lengths ~ 1 m

## Comparison of the LHC calorimeters' energy resolution

$$\frac{\sigma_E}{E} = \frac{a}{\sqrt{E}} \oplus \frac{b}{E} \oplus c$$

Sampling

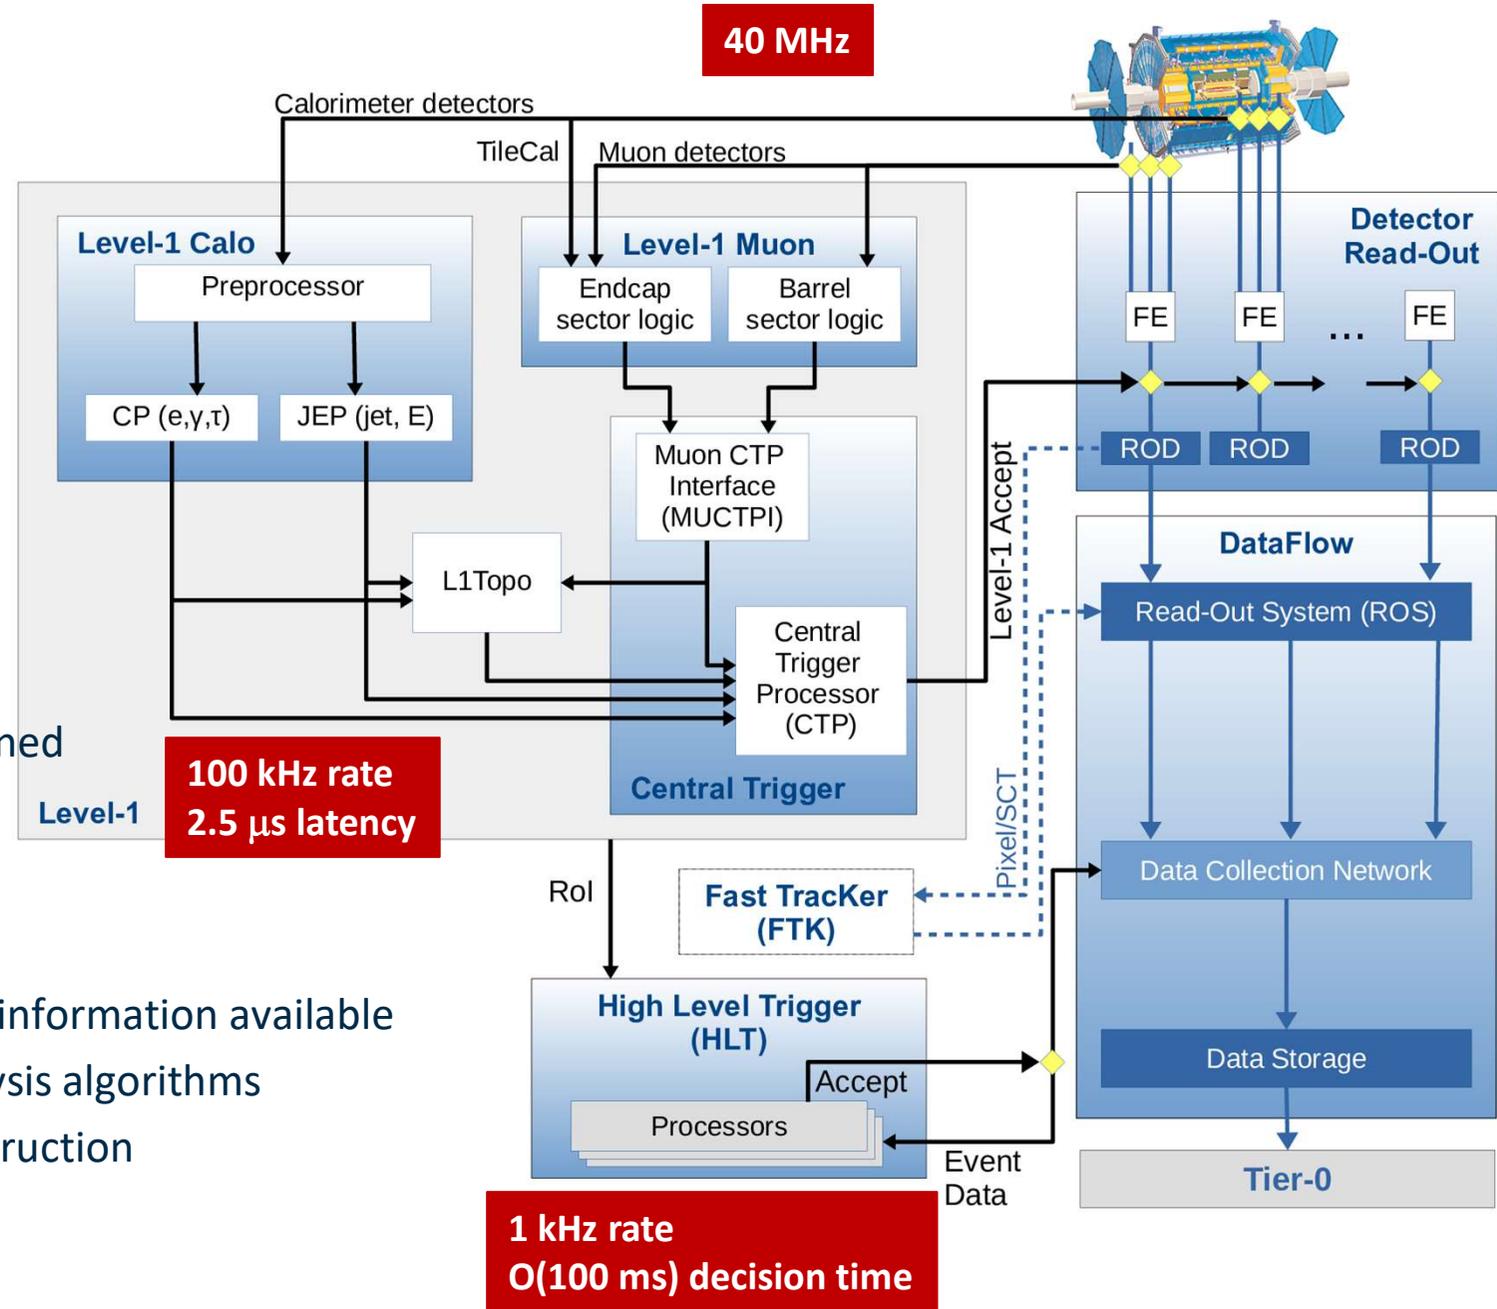

Noise

Calibration  
/ leakage

- Data reduction:
  - from 40 MHz bunch crossing rate
  - to ~1 kHz storage for offline analysis

- 1st level hardware trigger:
  - calorimeters
  - muon systems
  - only trigger components
  - initiate full detector readout within a predefined latency
  - ~100 kHz rate

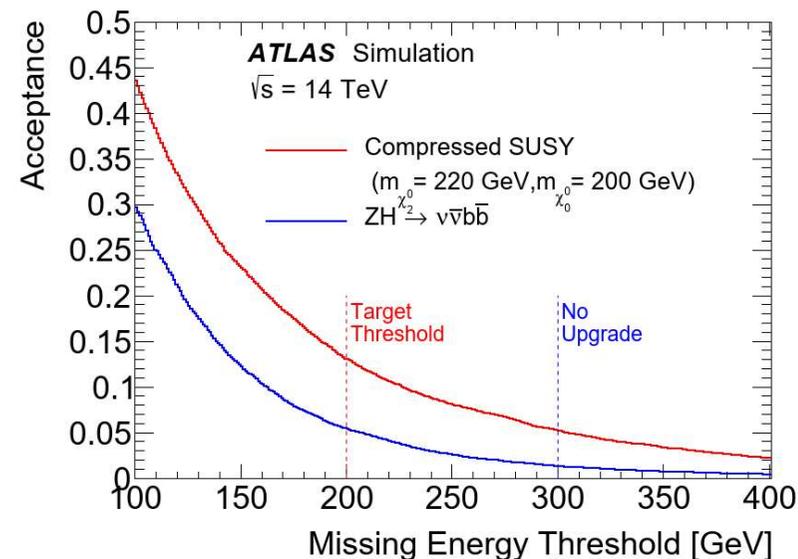

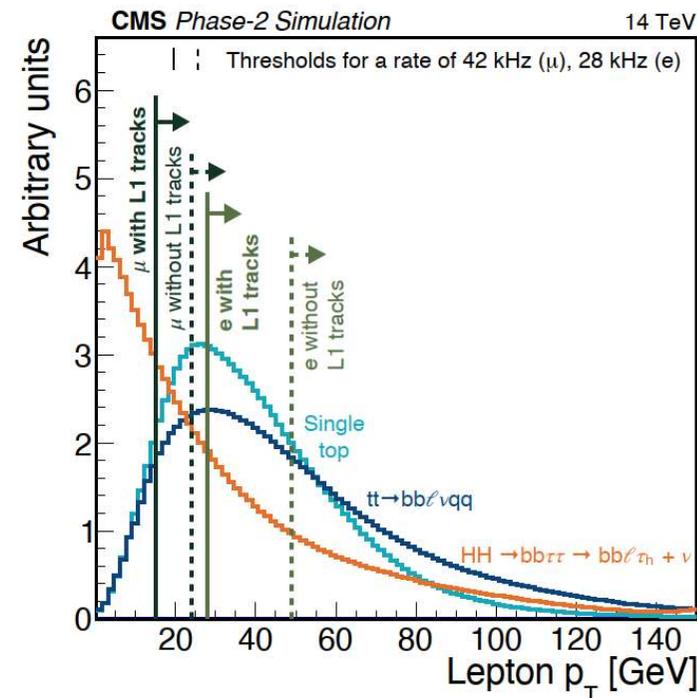

- High Level Trigger:
  - in principle full detector information available
  - streamlined offline-analysis algorithms
  - partial (regional) reconstruction

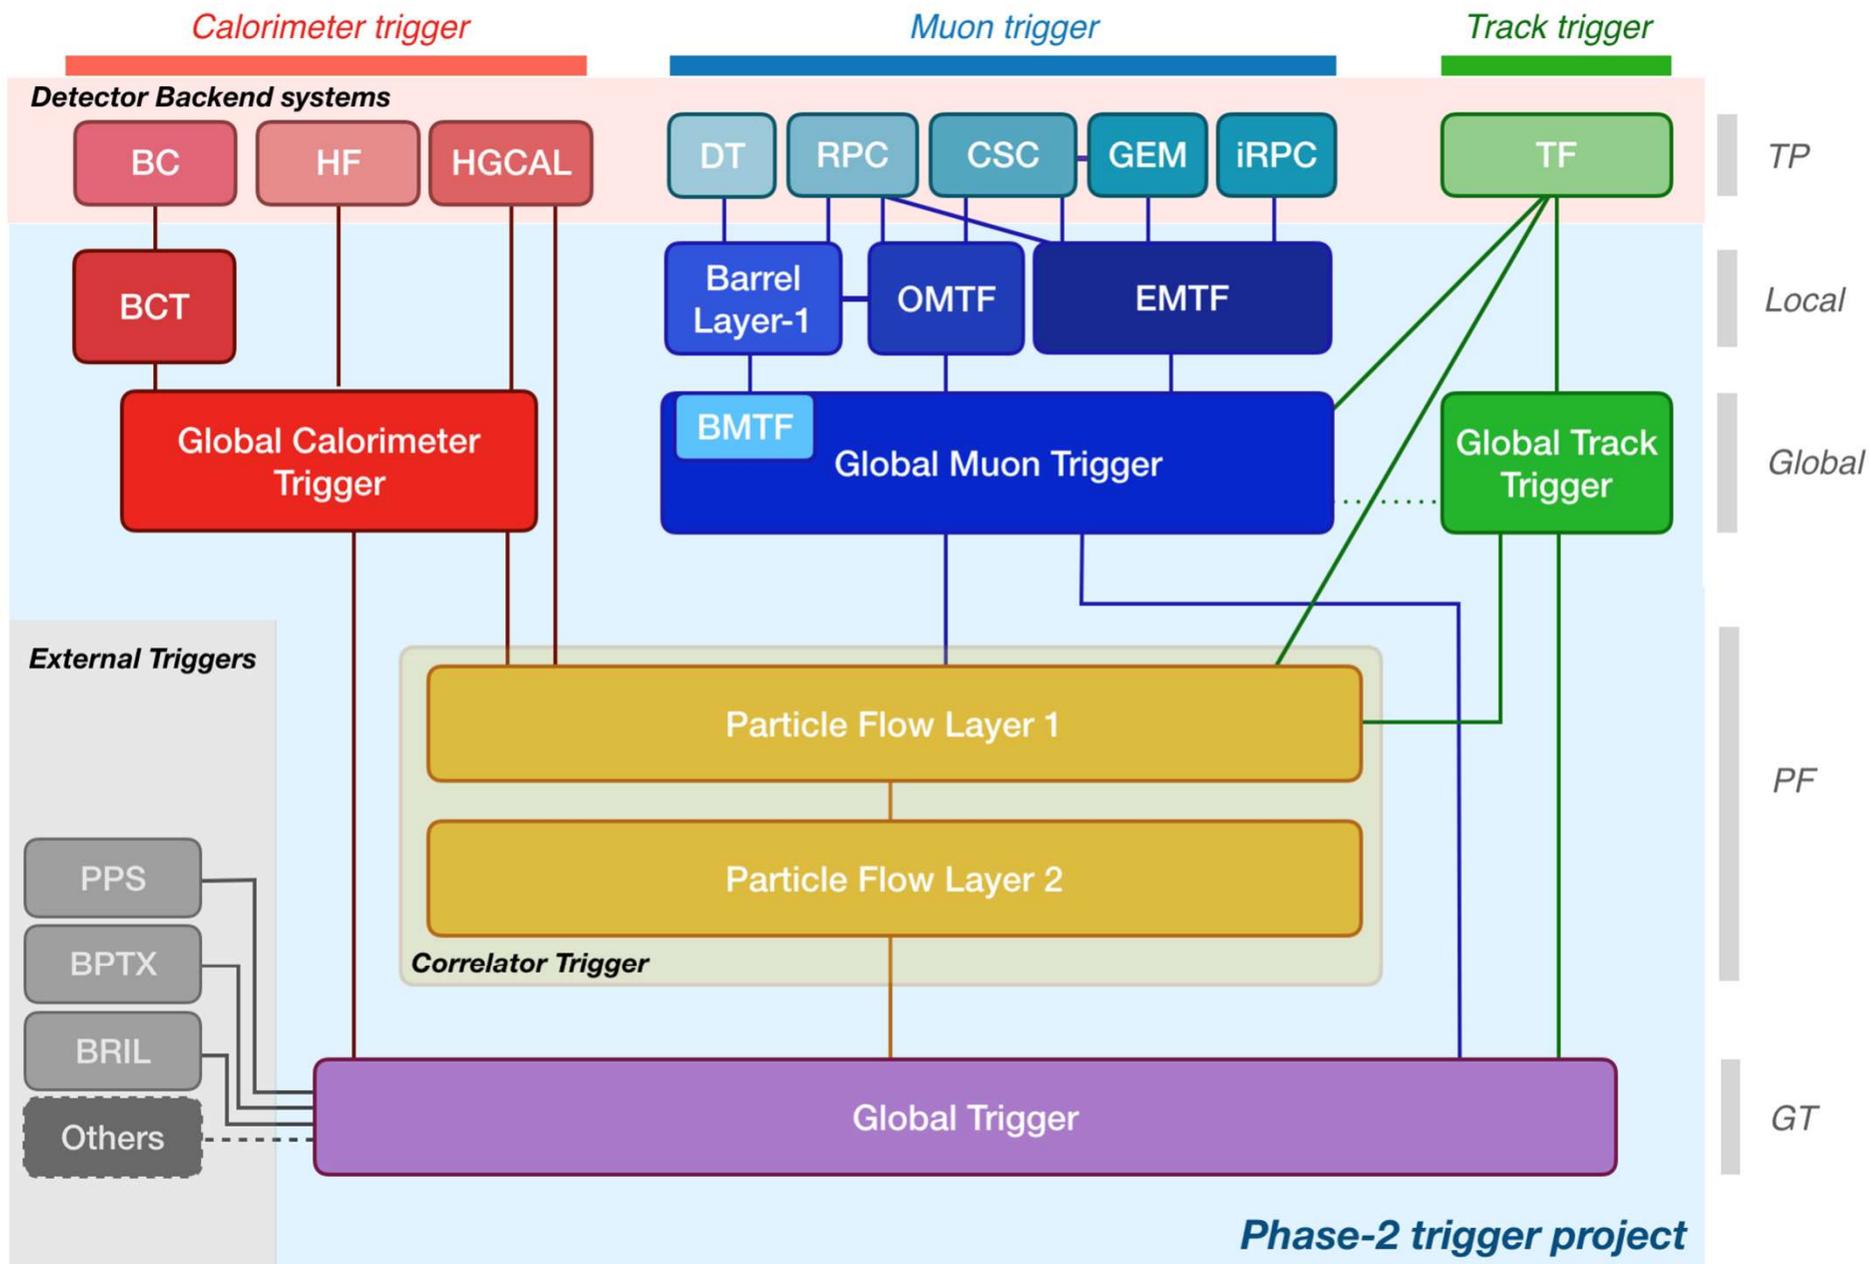

- **Trigger/DAQ**
  - Add tracking at first level trigger, exploit higher granularity
  - Improve bandwidth and processing for triggering, increase in latency
- **Tracking detectors**
  - New all silicon tracking detectors for ATLAS and CMS with extended coverage to  $|\eta| < 4$
- **Timing detectors** New at LHC
  - **ATLAS:** High granularity timing detector in front of forward calorimeter ATLAS
  - **CMS:** MIP timing layer around trackers
- **Calorimetry**
  - **ATLAS:** New FE electronics for Tile and LAr calorimeter (increase granularity)
  - **CMS:** New High Granularity Calorimeter (HGCal) in the endcaps and replace electronics in electromagnetic calorimeter
- **Muon system**
  - **ATLAS:** New FE electronics and additional units in muon spectrometer
  - **CMS:** Extend forward chambers and replace electronics

**For selected items: LHC technology → Upgrades for HL-LHC**

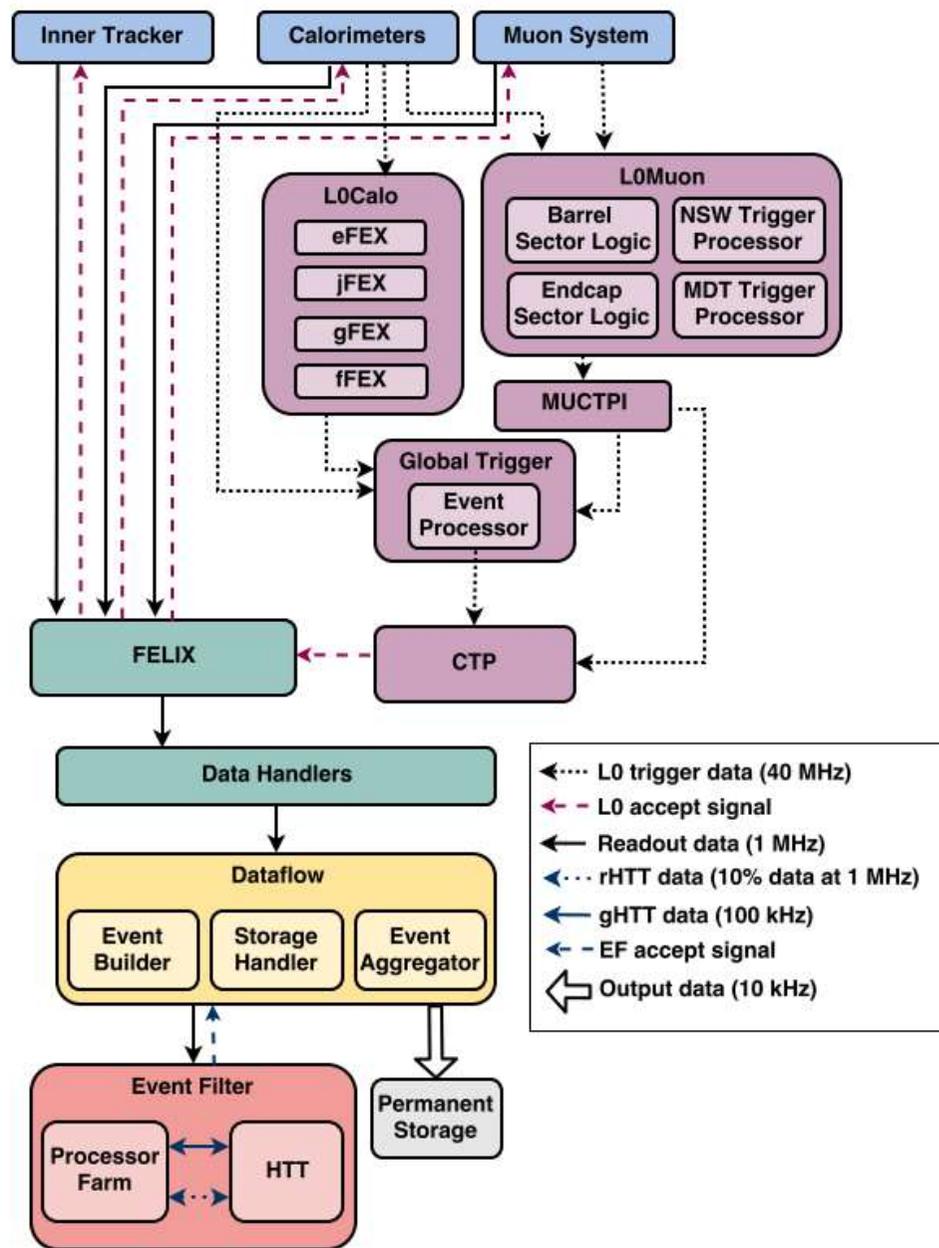

- Trigger selection defines the acceptance of physics measurements
  - compromise between **efficiency** (on interesting events) and **rate** (dominated by backgrounds)
- At HL-LHC:
  - **signal** proportional to luminosity increase
  - **background** increase due to higher pileup
  - even if improving the recording capability to 10 kHz, it is necessary to be **improve the background rejection**
  - more complex trigger algorithms require **longer latency**,  $\sim 2.5 \mu\text{s} \rightarrow \sim 12.5 \mu\text{s}$ : more memory needed to store data waiting for L1 decision
- **This will be a major driver on some detector upgrades:**
  - Improved trigger readout granularity
  - Fake reduction
  - Addition of tracking information at L1

DIPARTIMENTO DI FISICA

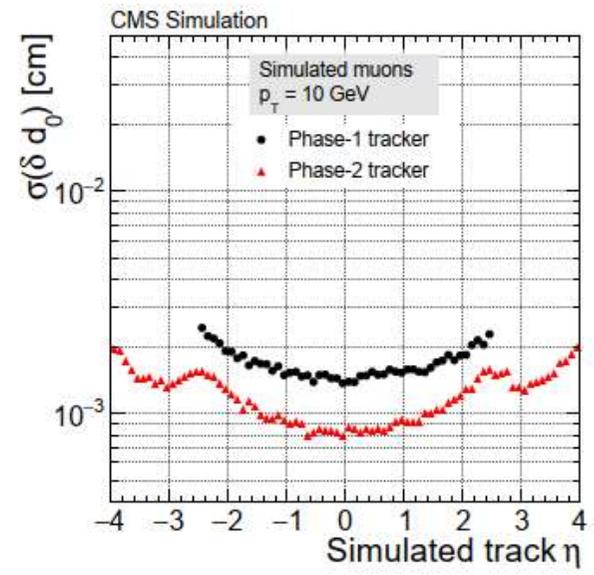

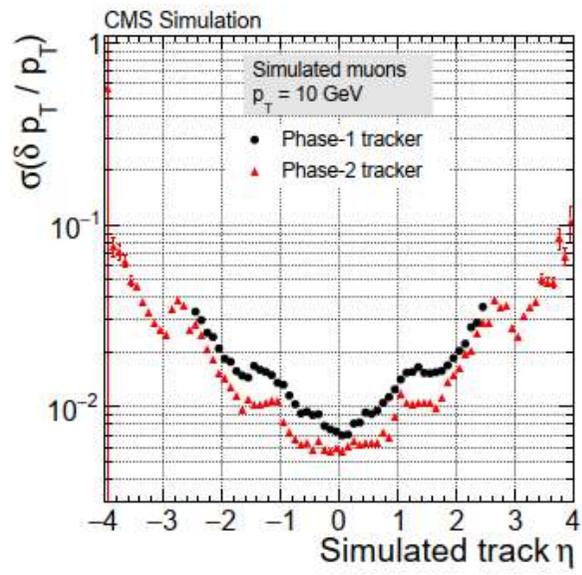

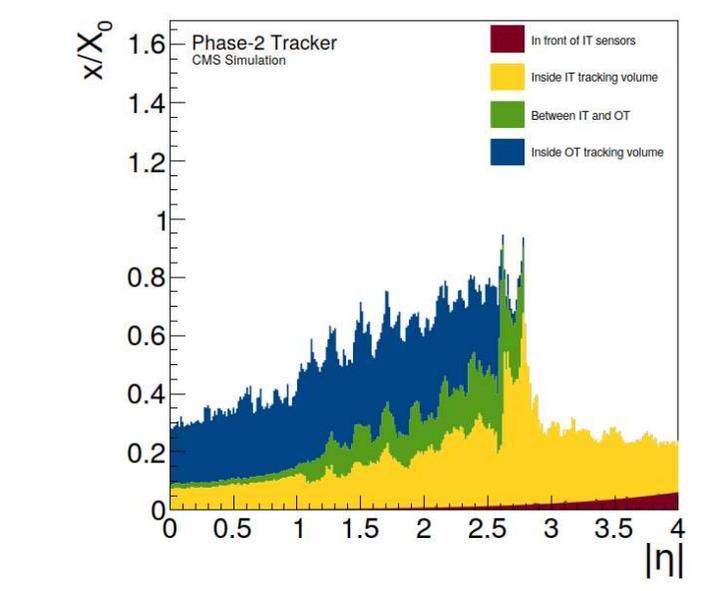

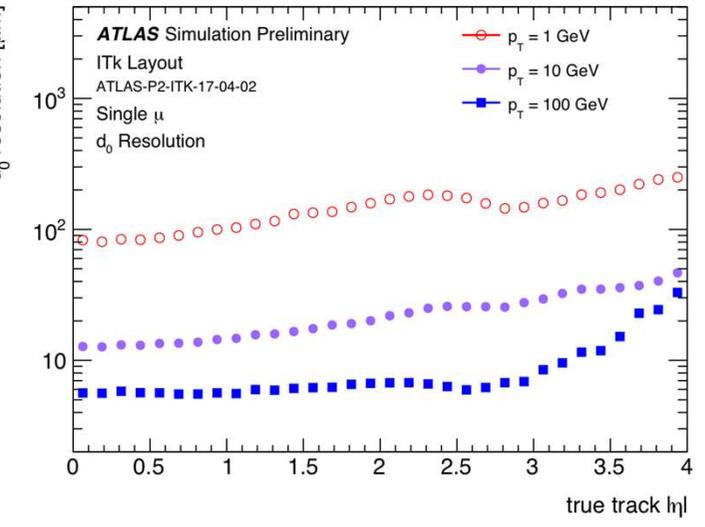

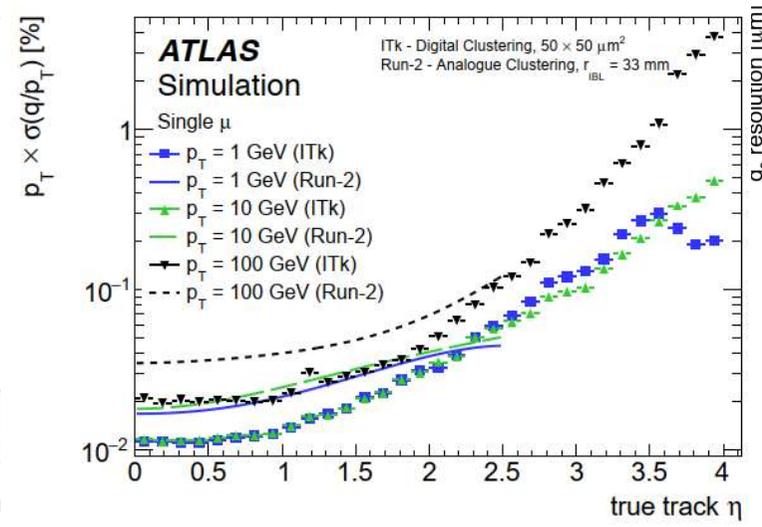

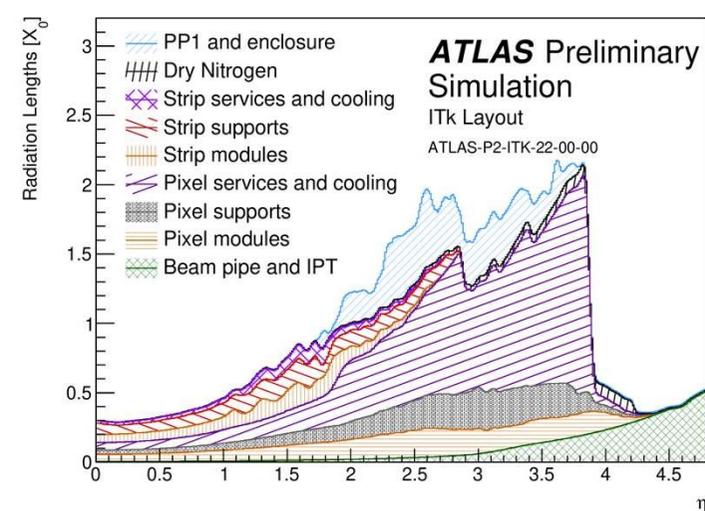

For HL-LHC, two completely new full-silicon tracking systems

- Extend tracking to  $|\eta|=4$
- n-in-p silicon sensors
- Increased particle flux+increased trigger rate:  
fast data transmission
- Rad-tolerant CMOS FE electronics:  
65 nm pixels, 130 nm strips
- Efficient power distribution:  
serial power in pixel, DC-DC converters in strip
- CO<sub>2</sub> bi-phase cooling
- Carbon structures: stability and low mass

	CMS	ATLAS
Strip pitch [ $\mu\text{m}$ ]	90-100	70-85
Strip length [cm]	2.5-5	2.5-8
Strip thickness [ $\mu\text{m}$ ]	300	300
Pixel size [ $\mu\text{m}^2$ ]	25×100 25×1500 (macro)	50×50 (25×100 in L0 barrel)
Pixel thickness [ $\mu\text{m}$ ]	<150	<150

# General layout e performance

- The simplest Silicon Detector is a reverse-biased *pn*-junction:

- The polarization creates a field that prevents diffusion of majority carriers in a depleted region
- Signal** is generated by electron-hole pair production by the energy loss of charged particles
- Leakage current** from thermal excitation

$$I_{leak} \propto T^2 e^{-\frac{E_g}{k_B T}}$$

- $T$  temperature
- $E_g$  band gap
- $k_B$  Boltzmann constant

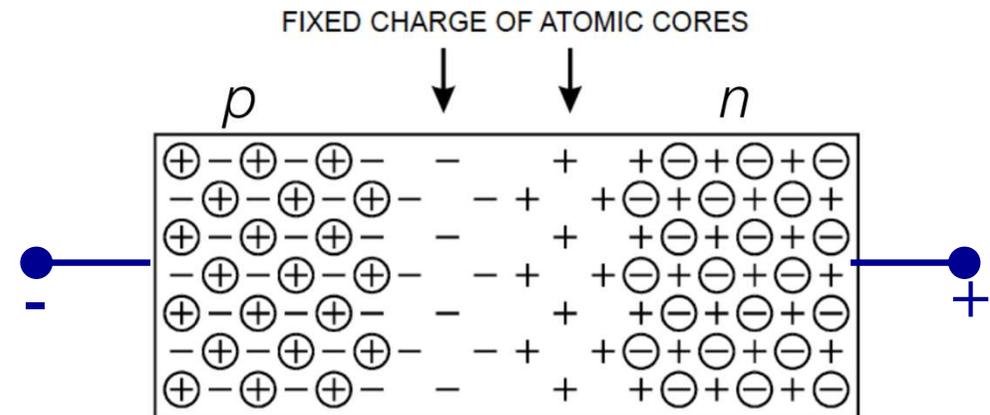

- A depleted region is created spontaneously also in absence of an external polarization:**

$$V_{BI} = \frac{k_B T}{e} \ln \left( \frac{N_A N_D}{n_i^2} \right)$$

25 mV at room T

Dopant densities  $10^{14-18} \text{ cm}^{-3}$

Intrinsic carriers density  $\sim 10^{13} \text{ cm}^{-3}$

- Relationships between bias voltage  $V_B$ , depletion  $d$ , electric field  $E$ , and dopant concentrations  $N_{A,D}$  can be obtained solving the Poisson equation:

$$\frac{dE_x}{dx} = \frac{\rho}{\epsilon}$$

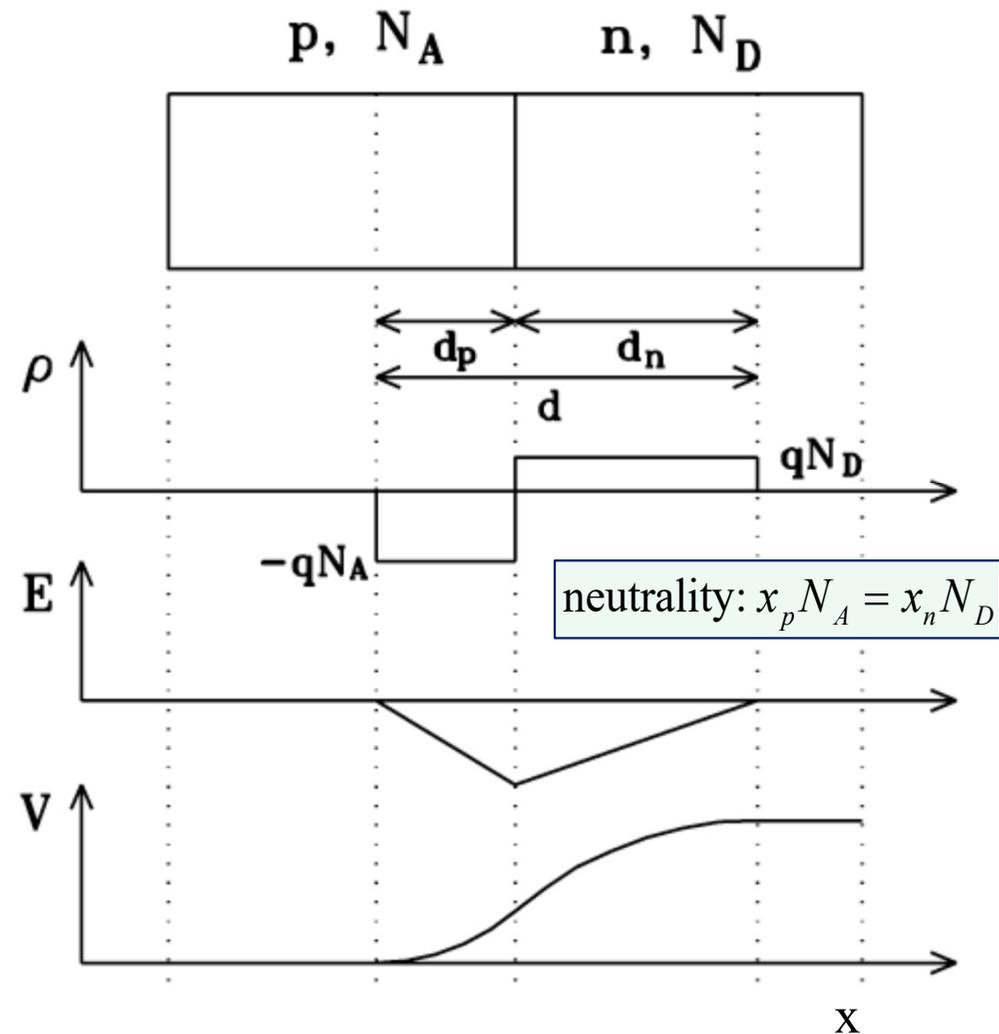

- Property determined by the less doped material

– assuming it is  $n$ -type:  $N_D \ll N_A$

$$E_{\max} = -\sqrt{\frac{2eV_B N_D}{\epsilon}}$$

$$d = x_p = \sqrt{\frac{2\epsilon V_B}{eN_D}}$$

$$C = \epsilon \frac{A}{d} = A \sqrt{\frac{\epsilon e N_D}{2V_B}}$$

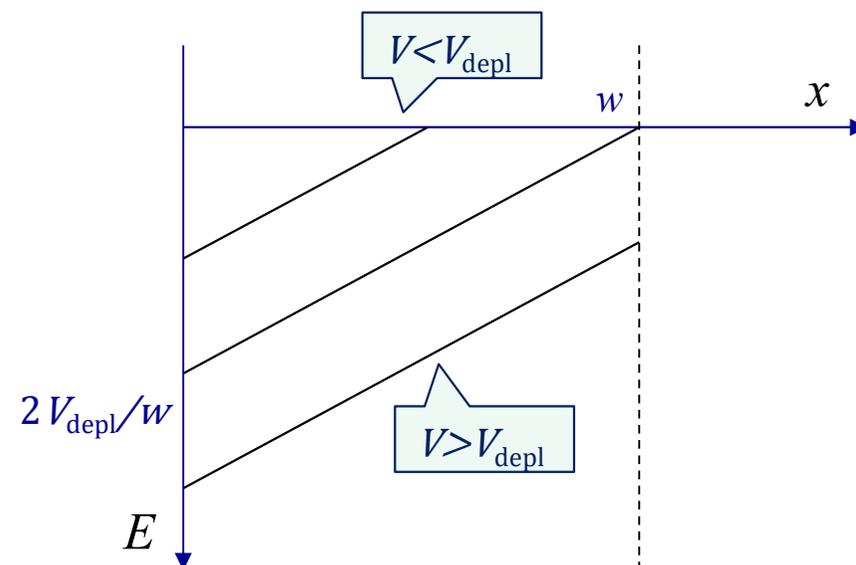

- Previous formulae are valid as long as the depleted region thickness  $d$  is smaller than the actual device thickness  $w$
- The depletion voltage  $V_{\text{depl}}$  is defined by  $x=w$ :

$$w = \sqrt{\frac{2\varepsilon V_{\text{depl}}}{eN_D}} \Rightarrow V_{\text{depl}} = \frac{w^2 e N_D}{2\varepsilon}$$

$$E(x) = -\frac{eN_D}{\varepsilon}(w-x) = -\frac{2V_{\text{depl}}}{w^2}(w-x)$$

- For  $V_B > V_{\text{depl}}$ ,  $E$  may change at most by a constant:

$$E(x) = -\frac{2V_{\text{depl}}}{w^2}(w-x) - \frac{V_B - V_{\text{depl}}}{w}$$

There is no region with null field: faster charge collection (see next slide)

- If  $n(\vec{x})$  and  $p(\vec{x})$  are inhomogeneous concentrations of free electrons and holes, their corresponding current densities  $J$  are:

$$\begin{aligned}\vec{J}_p &= qp\mu_h\vec{E} - qD_p\vec{\nabla}p \\ \vec{J}_n &= -qn\mu_e\vec{E} + qD_n\vec{\nabla}n \\ \vec{J} &= \vec{J}_p + \vec{J}_n\end{aligned}$$

- The drift velocities are

$$\begin{aligned}v_{D,h} &= \mu_h E \\ v_{D,e} &= -\mu_e E\end{aligned}$$

- Relationships are linear as far as

$$v_D \ll v_{\text{thermal}}$$

- above  $v_D$  saturates at approximately  $0.8 \times 10^7$  cm/s

- In the linear region the mobility  $\mu$  is related to the collision time  $\tau_c$  and the effective carrier mass  $m^*$ :

$$\begin{aligned}\mu_h &= \frac{q\tau_c}{m_h^*} \\ \mu_e &= \frac{q\tau_c}{m_e^*}\end{aligned}$$

- in this situation also holds Einstein's relation:

$$D_{p,n} = \frac{k_B T}{q} \mu_{h,e}$$

- At room temperature:

- $\mu_h = 480$  cm<sup>2</sup>/Vs
- $\mu_n = 1350$  cm<sup>2</sup>/Vs

- A useful relation is the resistivity

$$\rho = \frac{1}{q(n\mu_e + p\mu_h)}$$

- assuming it is  $n$ -type,  $N_D \ll N_A$ :  $\rho = \frac{1}{N_D \mu_e}$   
which is a macroscopical measurable quantity (unlike  $N_D$ )

- Similar to gas discharges, it is possible to achieve charge multiplication when the energy gained between two collisions is larger than the excitation energy.

$$\begin{aligned}\Delta E_{\text{kin}} &= -q\Delta V \approx qE\Delta x \\ &= |qE v_{\text{drift}} \tau_c| = |q| E^2 \mu \tau_c\end{aligned}$$

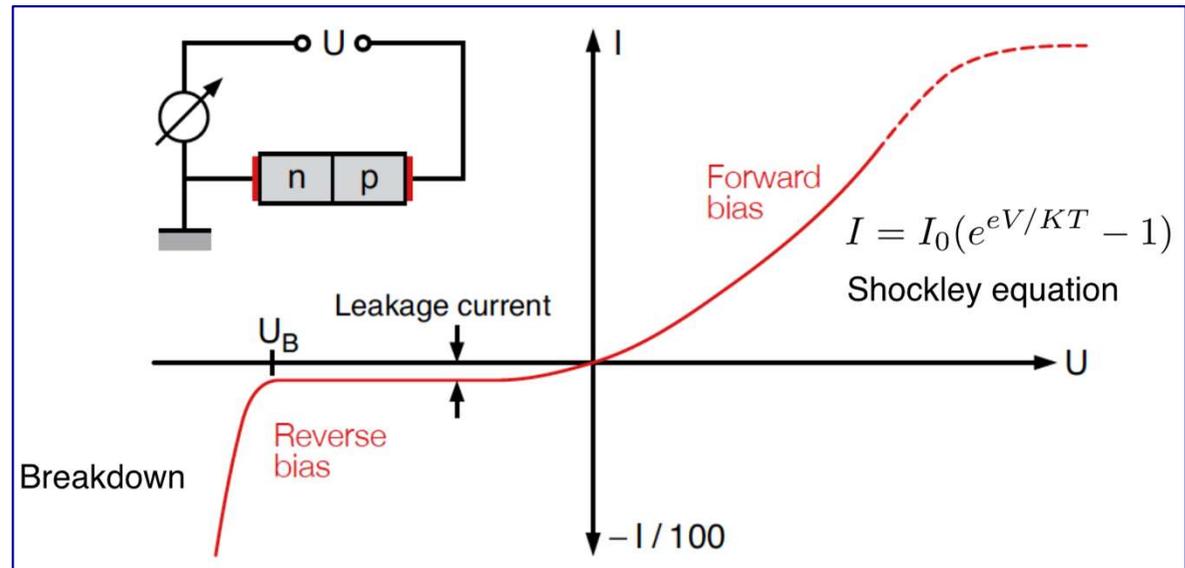

$$\Delta E_{\text{kin}} > E_G \Rightarrow E_{\text{bd}} = \sqrt{\frac{E_G}{q\mu\tau_c}}$$

–  $E_{\text{bd}} \approx 3 \times 10^5 \text{ V/cm}$

- The maximum value of the field is at the junction:

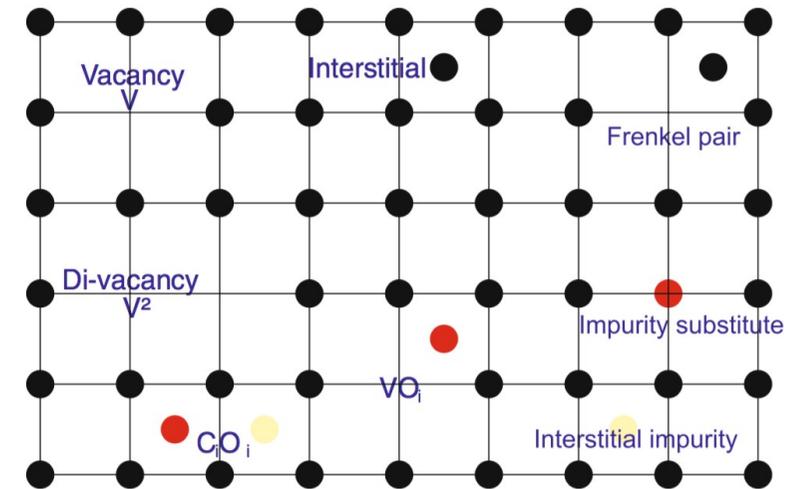

$$E(0) = \frac{eN_D x_n}{\varepsilon} = \frac{1}{\varepsilon \rho \mu_e} \sqrt{2\varepsilon \rho \mu_e V_0} = \sqrt{\frac{2V_0}{\varepsilon \rho \mu_e}} \quad V_{\text{bd}} = \frac{\varepsilon \rho \mu_e}{2} E_{\text{bd}}^2$$

- **In real life dominated by implantation shapes and defects.**

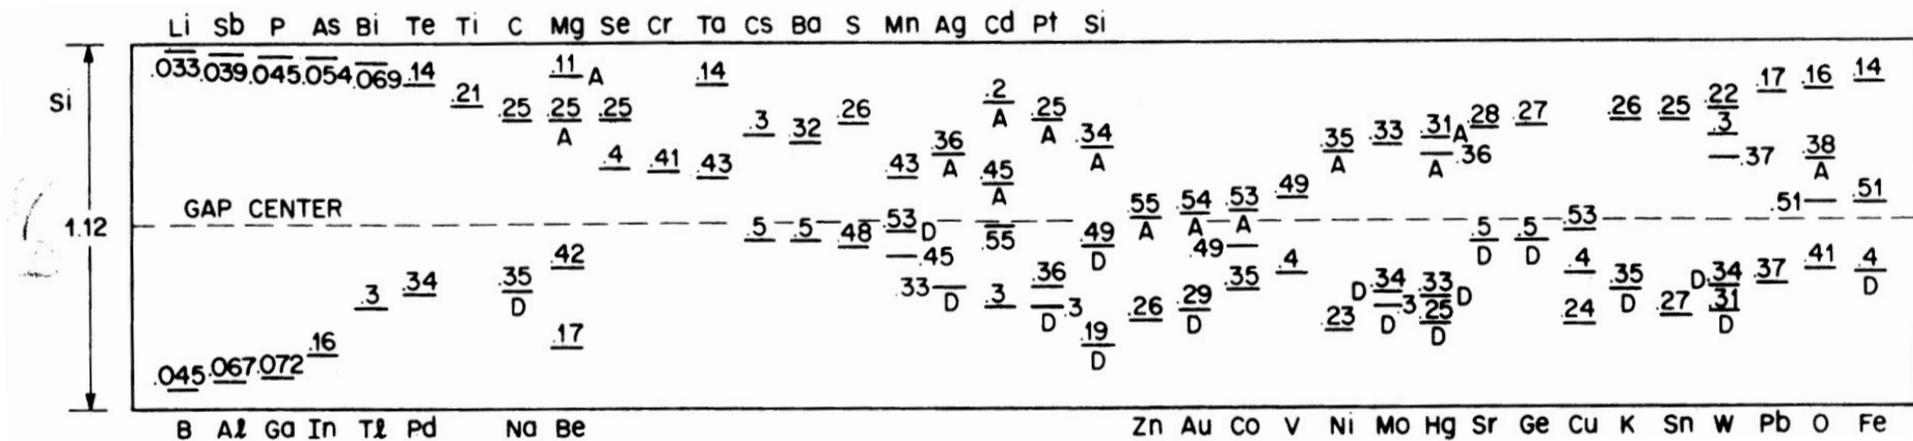

- The most critical requirement for operation at the HL-LHC is **radiation hardness**
- Two main radiation effects:
  - **Bulk damage:** damage of the crystal lattice
    - increase of leakage current
    - change of “effective” doping concentration
    - trapping of charge carriers
    - depends on Non-Ionizing Energy Loss (NIEL)
    - measured relatively to the one induced by a fluence of 1 MeV neutrons
  - **Surface damage:** concentration of surface charge
    - affecting the electric field and breakdown voltage
    - proportional to Total Ionization Dose (TID)

- Bulk damage is mainly induced by displaced atoms
- Production of several energy levels in the band gap
- Defect may diffuse: it changes with time

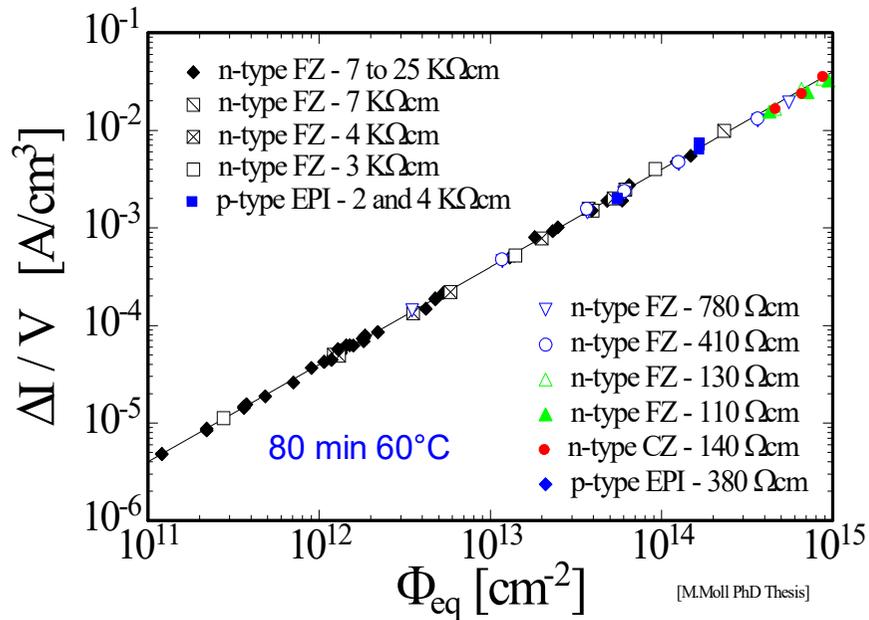

## Example : Energy Levels of impurities in Si

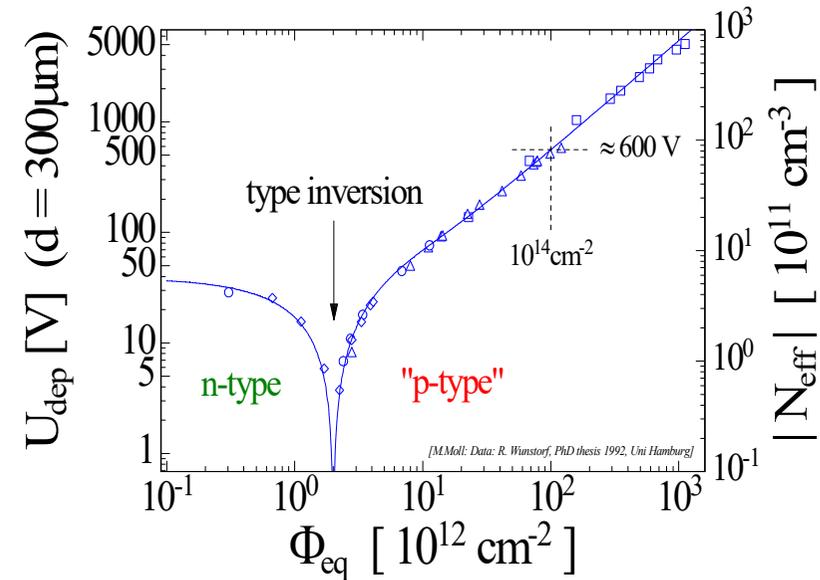

Da: S. M. Sze, Physics of Semiconductor Devices, Wiley & Sons, Singapore, 1981

## Leakage current

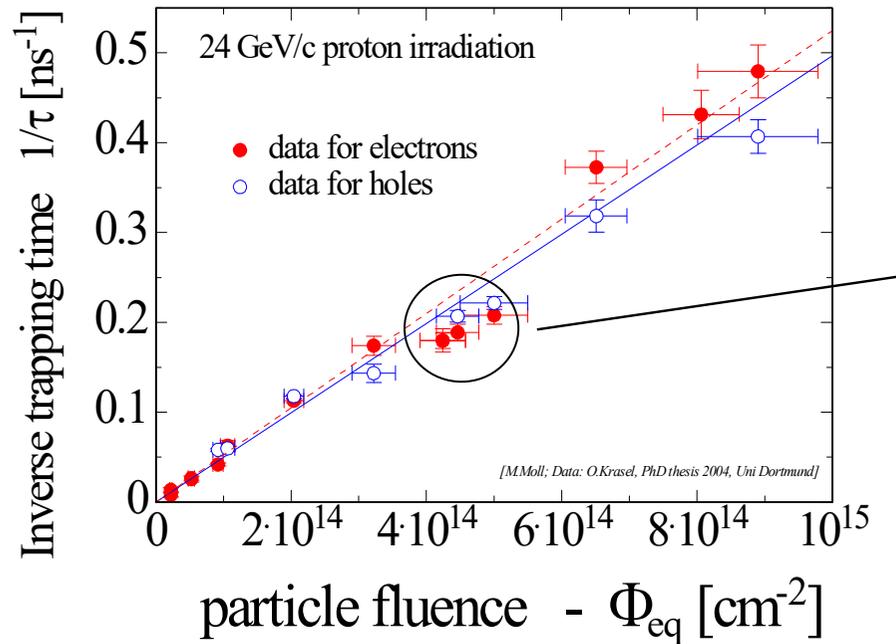

- Increasing leakage current:
  - source of noise in the readout electronics  $\sqrt{I}$
  - increase power dissipation
- Reduce detector operational temperature

## Effective doping concentration

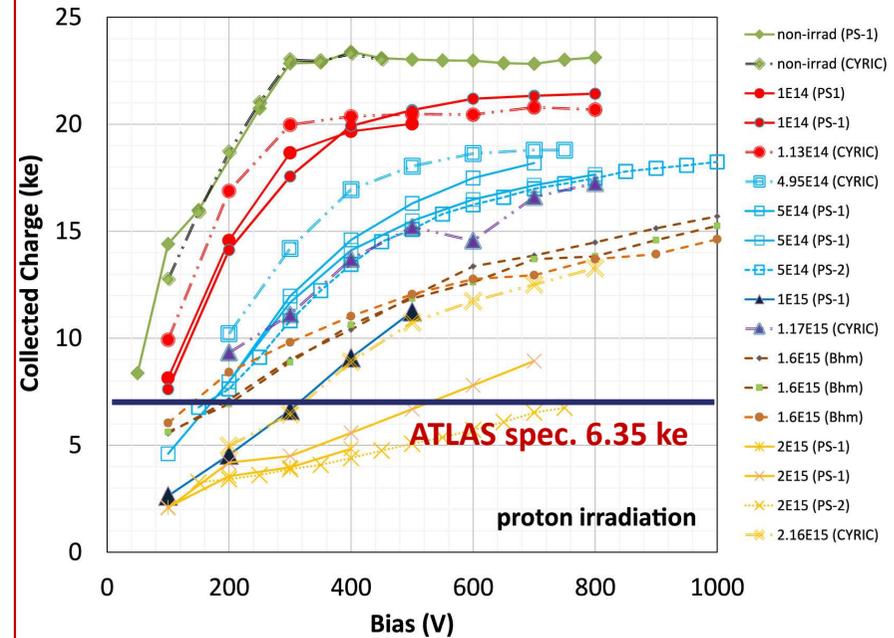

- Increasing the amount of defects increase the electric field needed to deplete the detector
- Smears out gradients of doping concentration:
  - higher breakdown voltage

## Trapping time

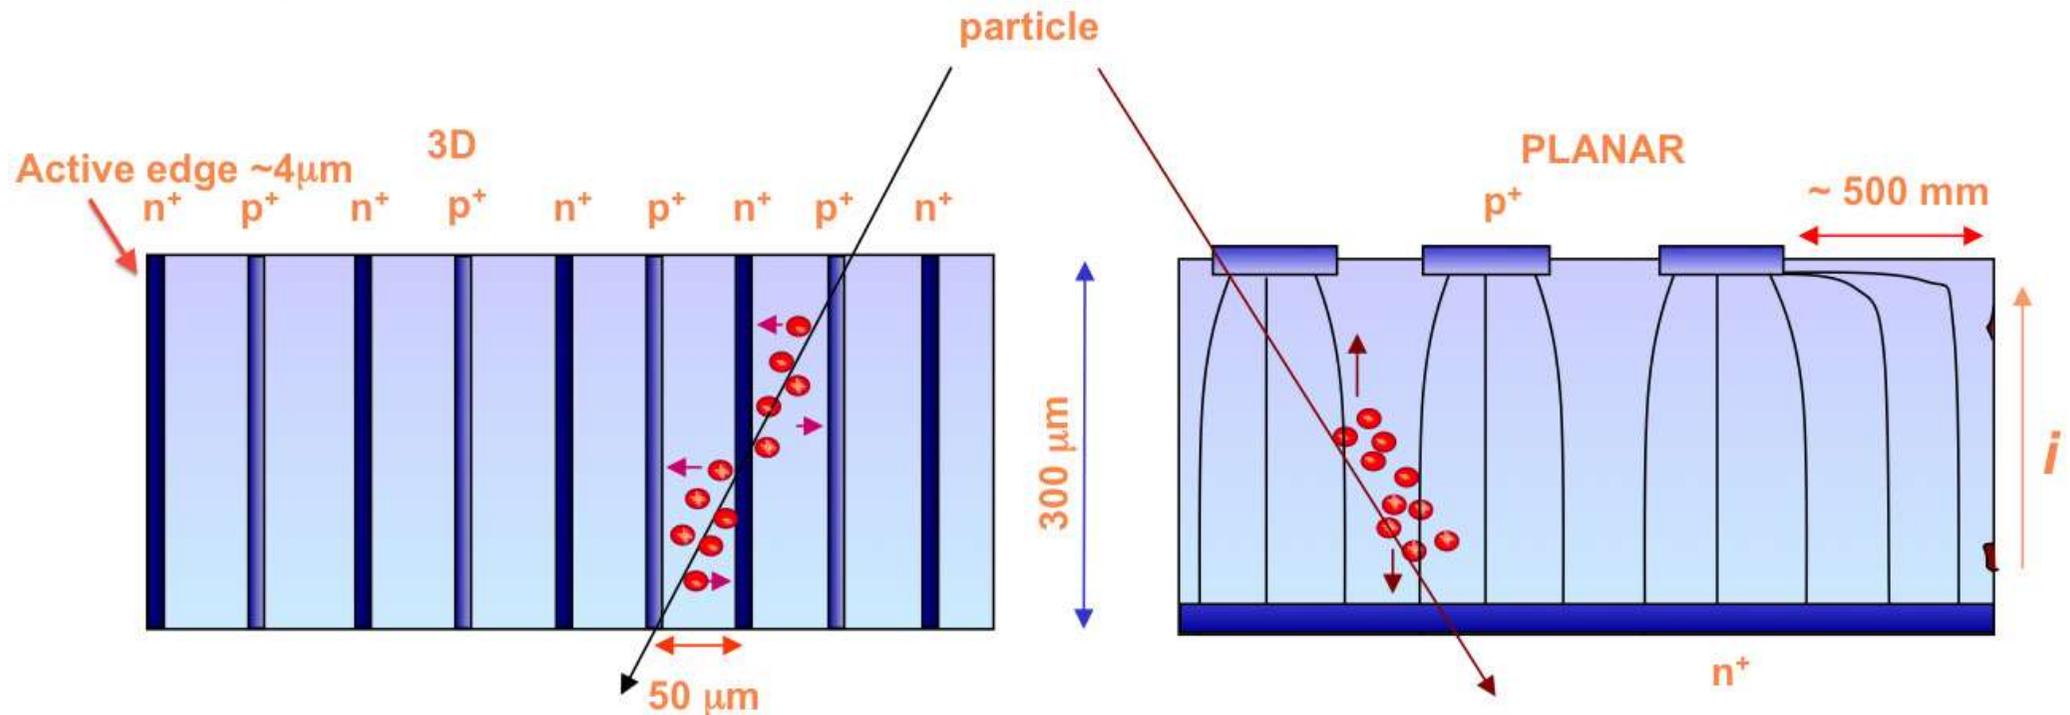

- Trapping probability per unit time:
  - The longer the collection time the more likely charge carriers are lost
- Increase applied electric field
- Thin sensors behave better

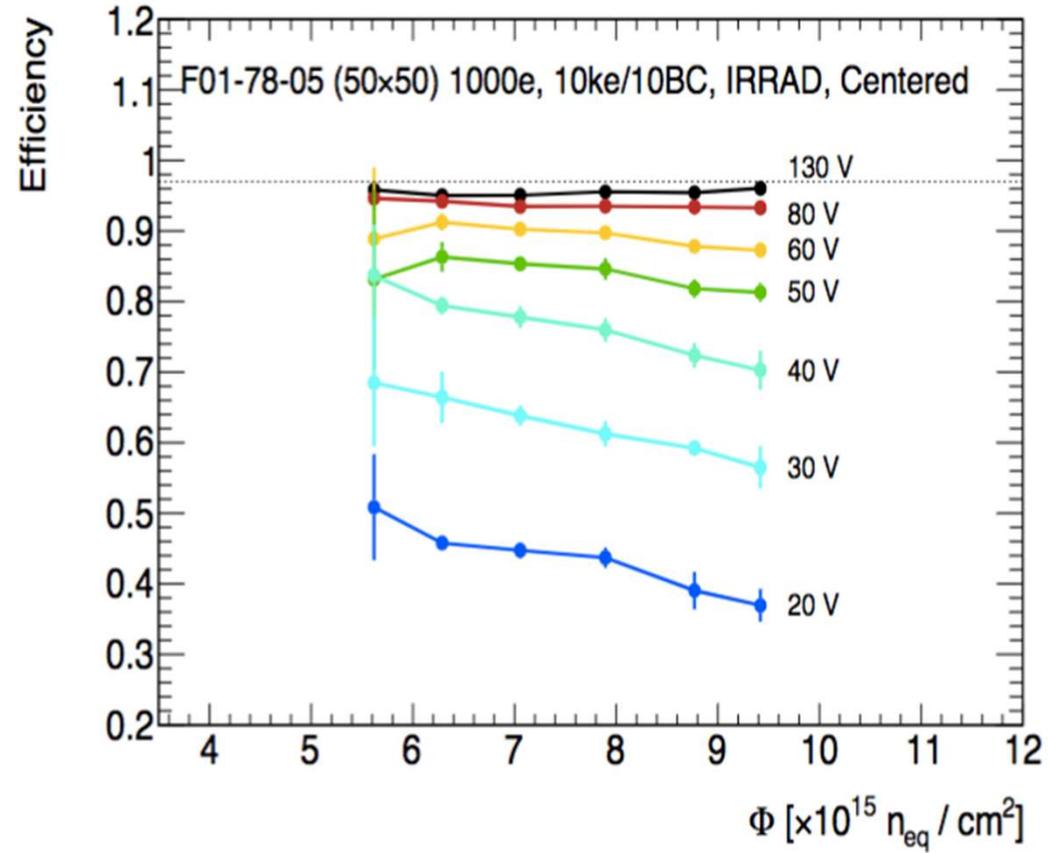

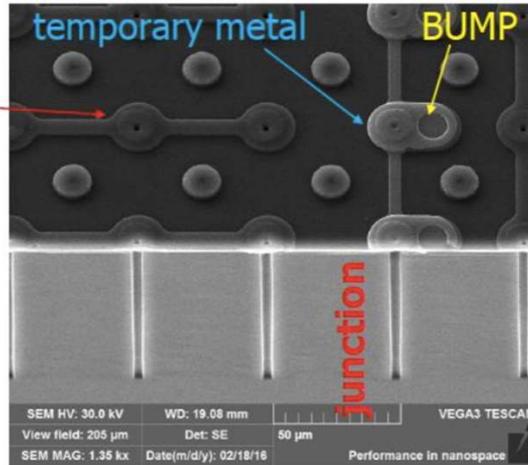

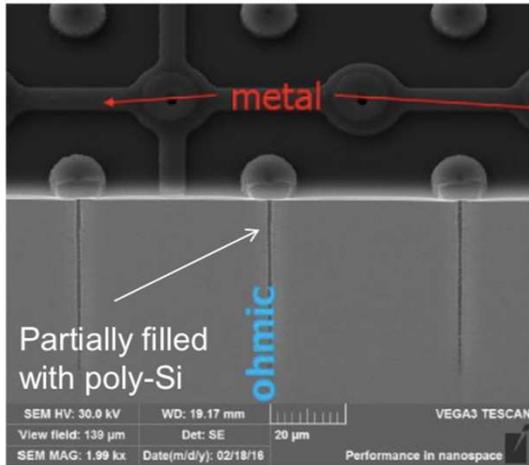

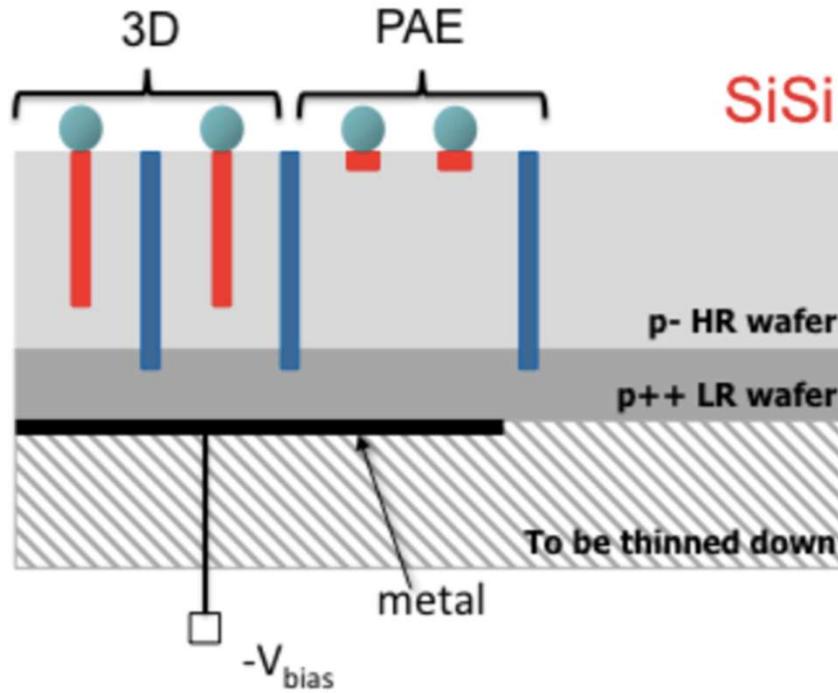

## Example

- ATLAS Strip sensor:
  - 320  $\mu\text{m}$  thick silicon
  - 75.5  $\mu\text{m}$  strip pitch

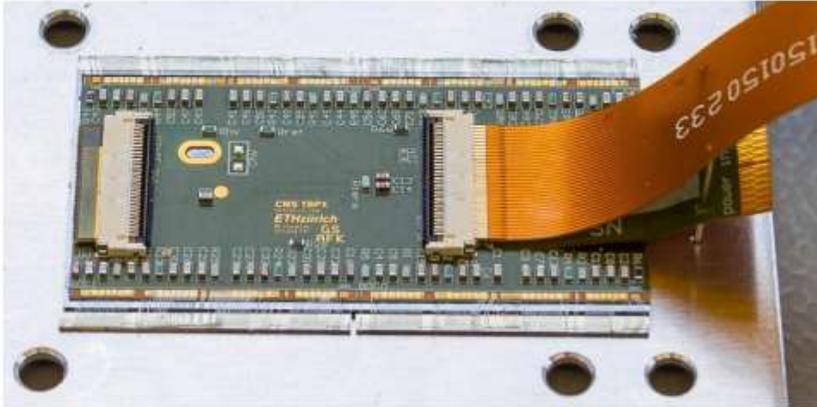

- The radiation level is particularly severe for detectors near to the interaction region:
- 3D detectors are an option to increase radiation hardness by improving charge collection
  - larger capacitance (higher noise)
  - more complex fabrication steps
  - preferred choice for innermost layers

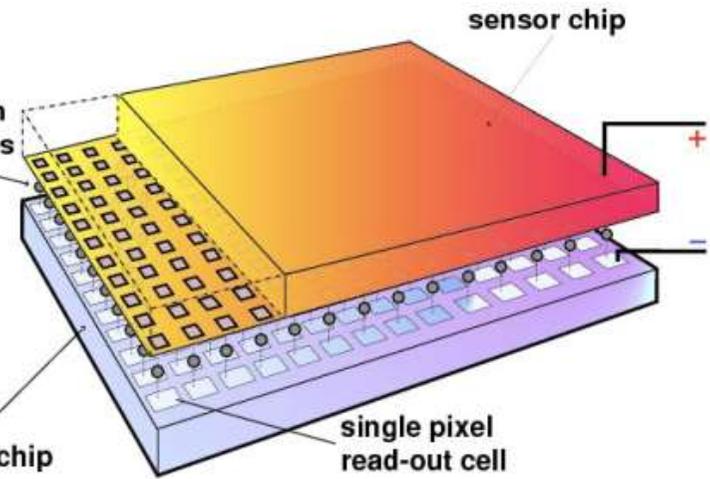

# How real modules looks like

solder bumps

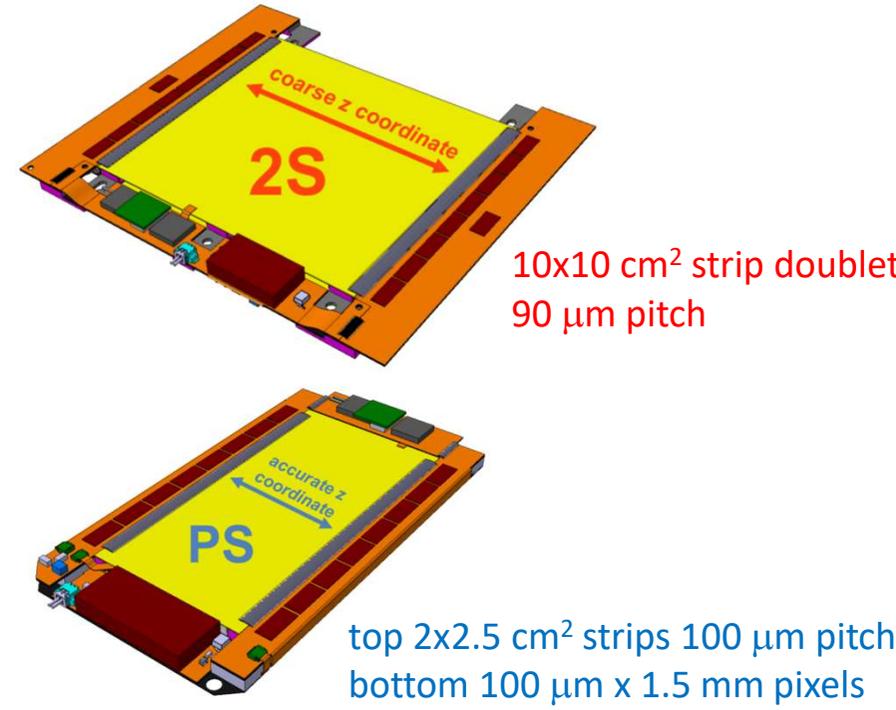

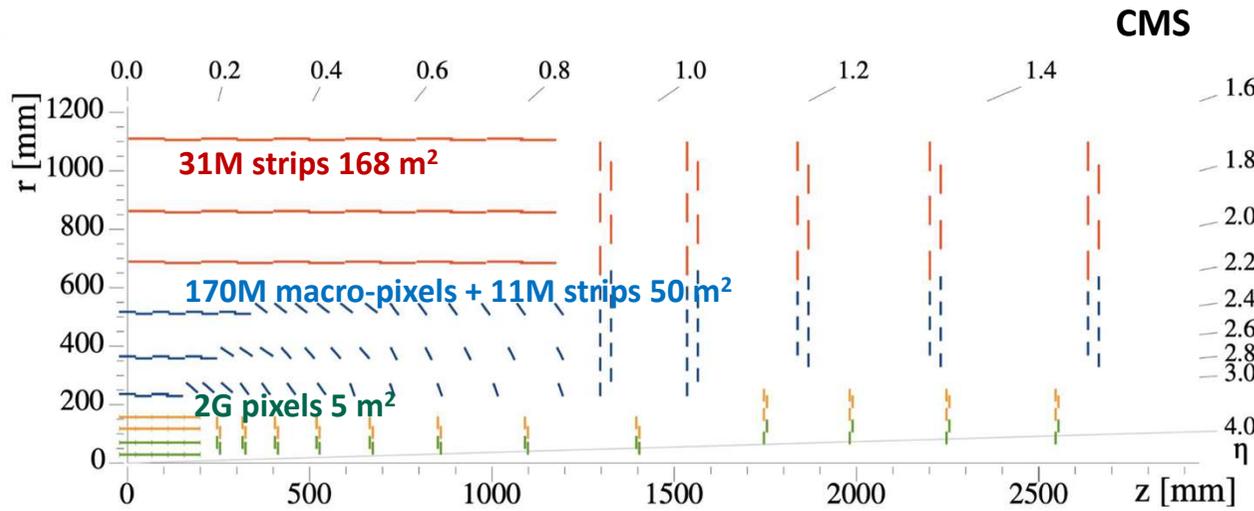

read-out chip

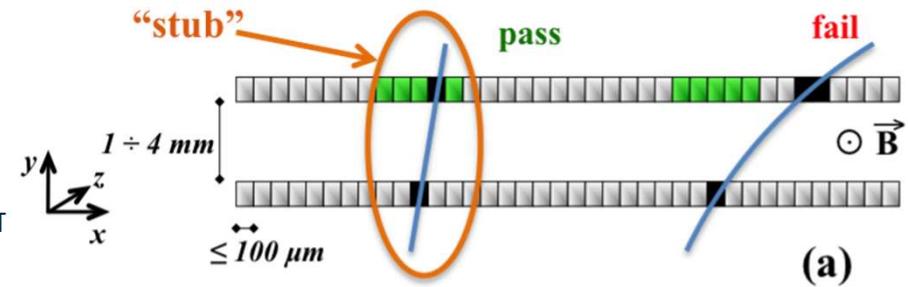

ATLAS Strips

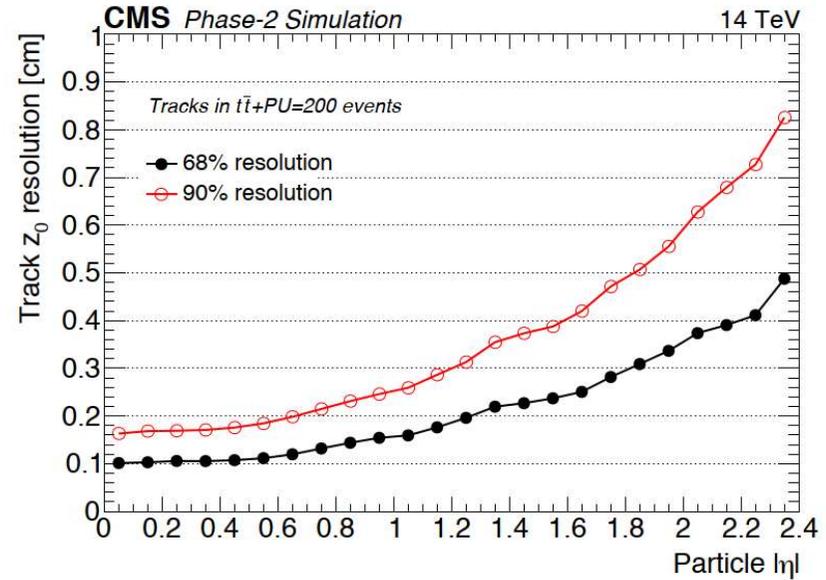

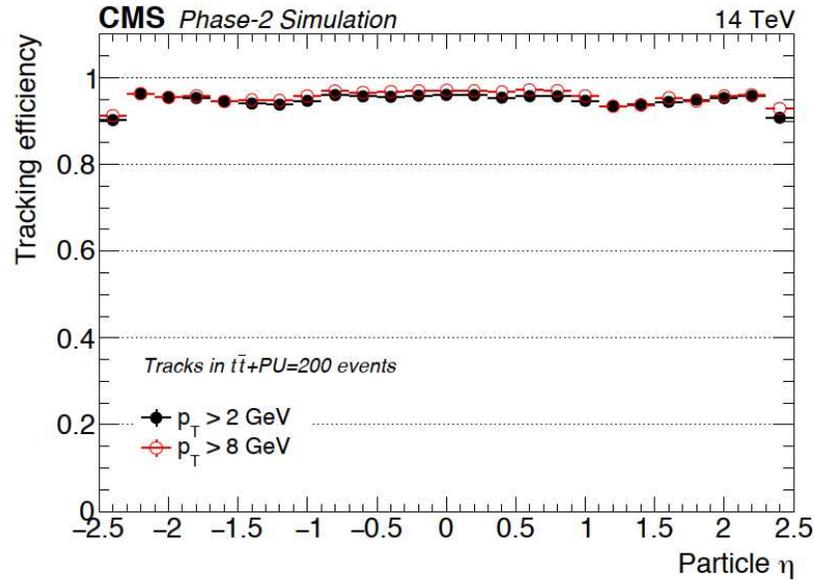

## CMS $p_T$ module concept

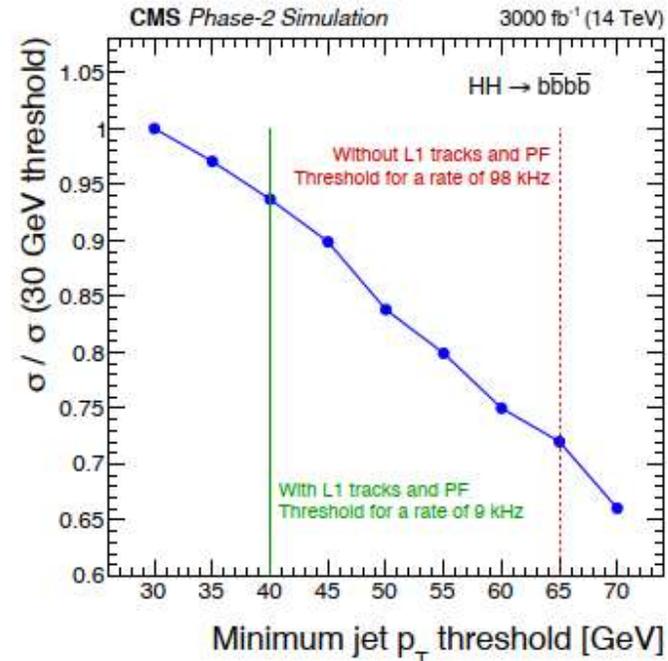

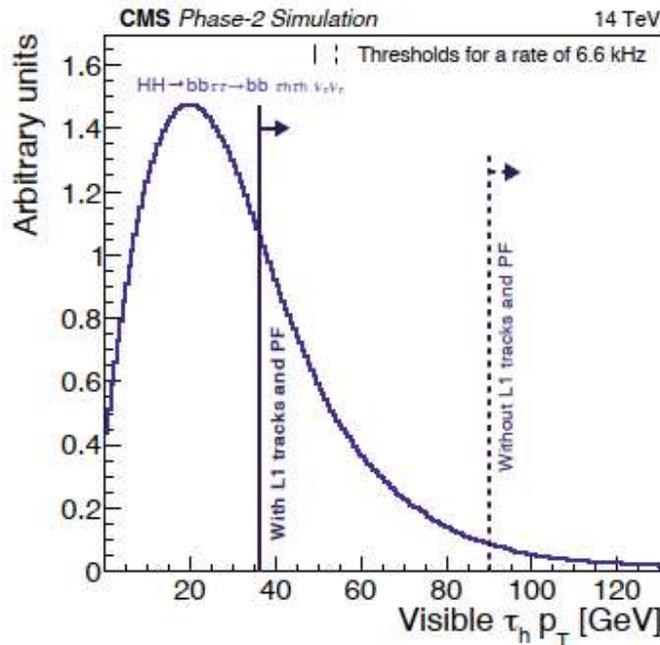

- $p_T$  discrimination in FE electronics by providing correlations between closely spaced doublet of sensors.
- Send to trigger only "stubs" (hit pairs) compatible with particle of  $p_T > 2 \text{ GeV}/c$
- Data reduction by factor 10-20:
  - at HL-LHC expect 7000 tracks/BX, but only 200 with  $p_T > 2 \text{ GeV}/c$
  - still data rate of 30 TB/s, and 15k stubs to start pattern recognition
- Highly parallel processing + full FPGA based system

Track Reconstruction

Application to  $HH \rightarrow bb\tau\tau$

# TIMING MEASUREMENTS

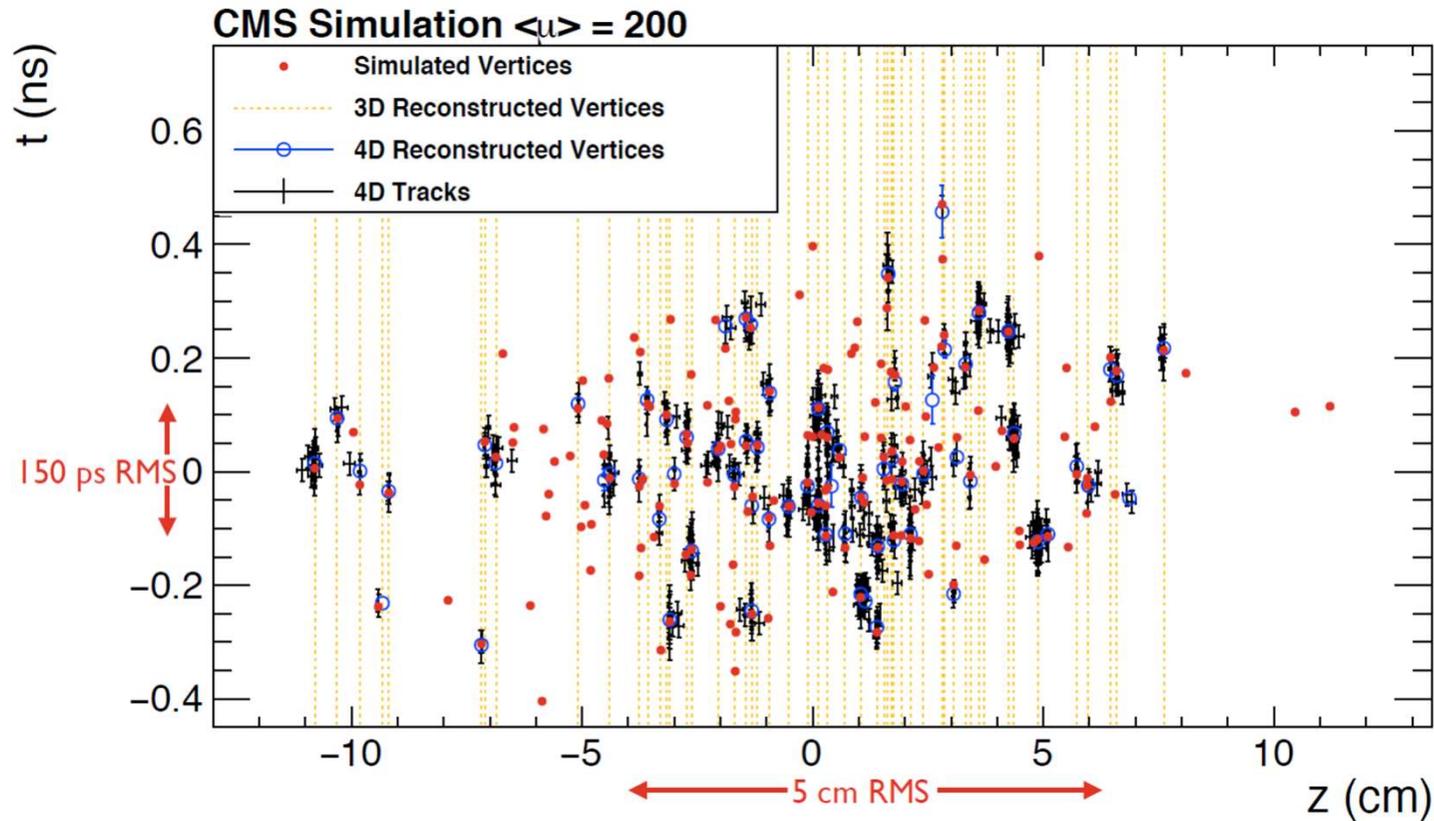

Istituto Nazionale di Fisica Nucleare

**Sezione di Milano**

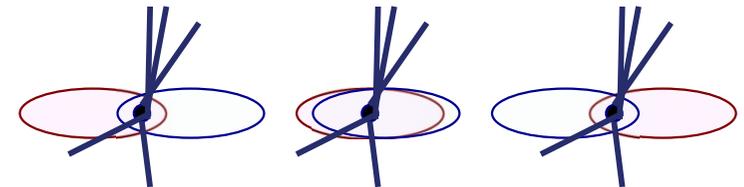

**UNIVERSITÀ DEGLI STUDI DI MILANO**  
DIPARTIMENTO DI FISICA

# Timing motivations

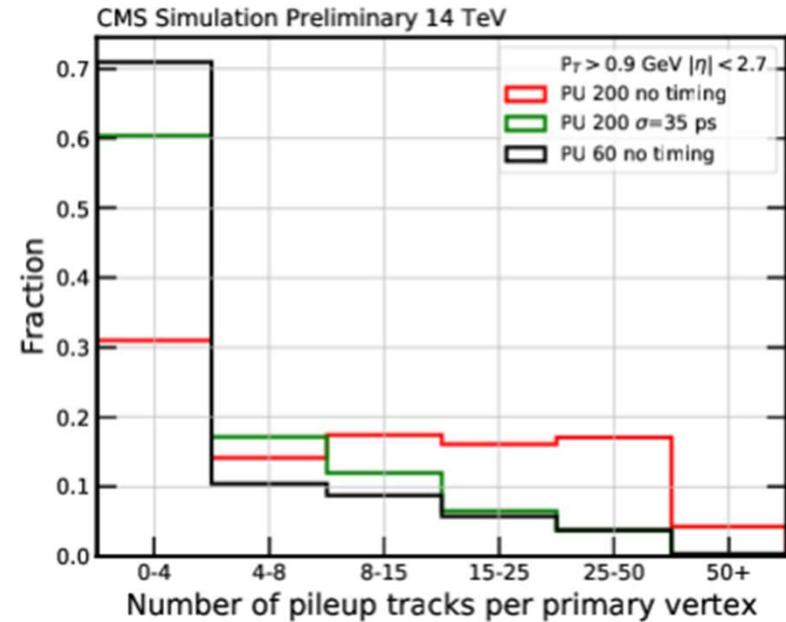

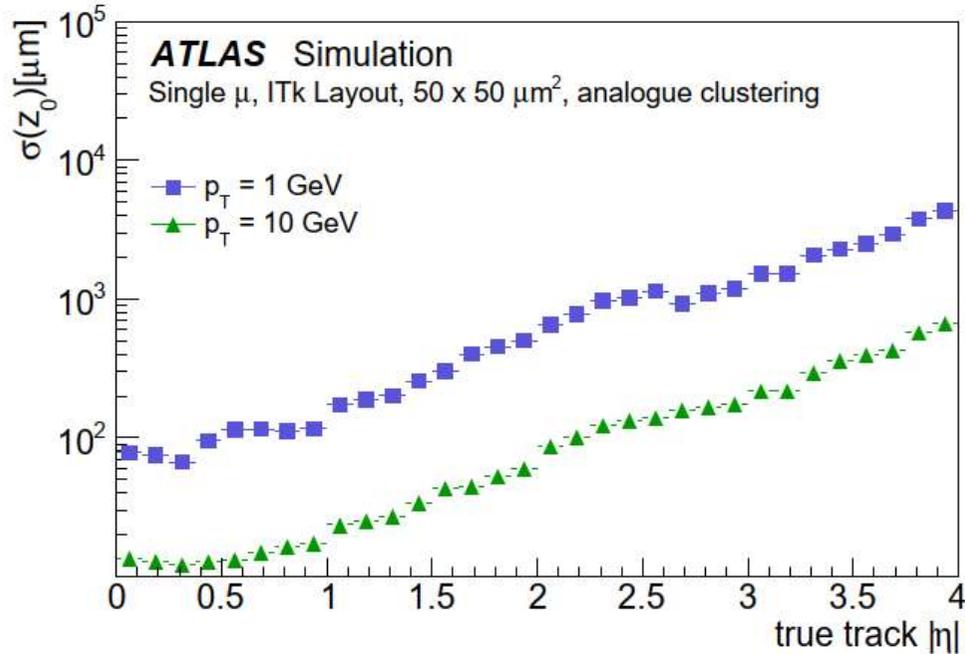

- Vertex density at HL-LHC does not allow to reconstruct primary vertices by spatial information alone.
- Due to the finite size of the bunch, interactions do not happen all at the same time but have a distribution with standard deviation

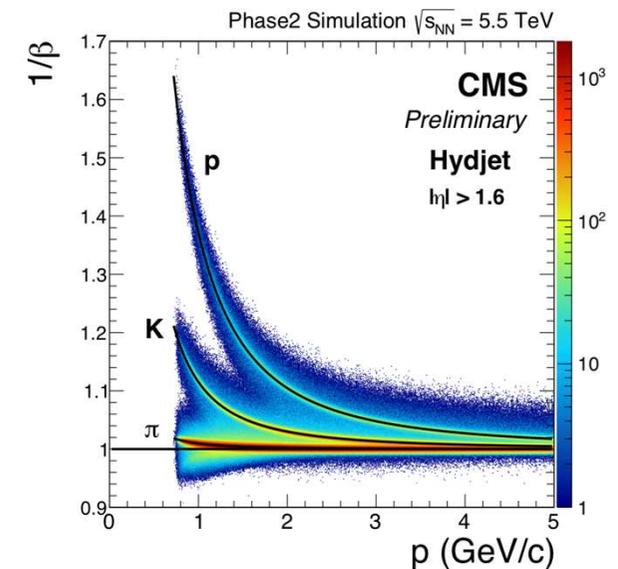

$$\sigma_t = \frac{\sigma_z}{c} \approx \frac{5 \text{ cm}}{c} \approx 180 \text{ ps}$$

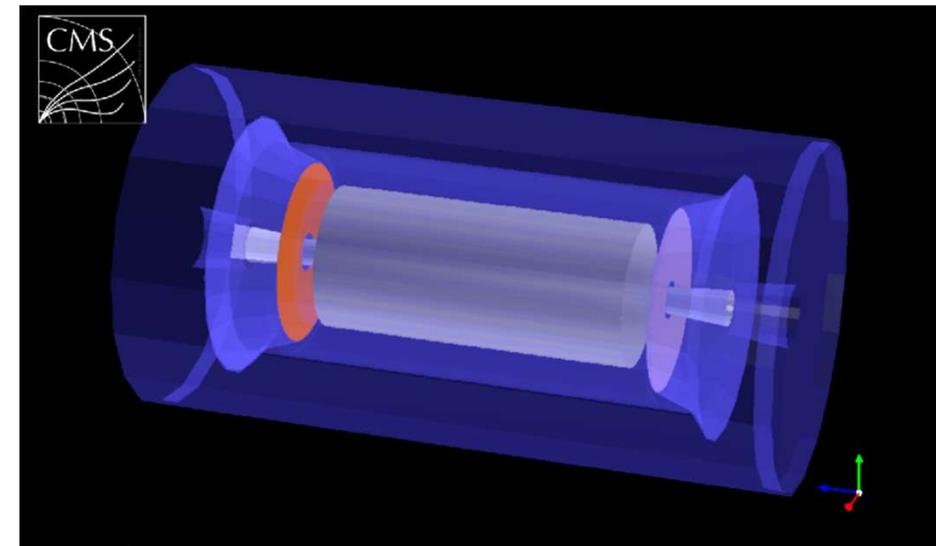

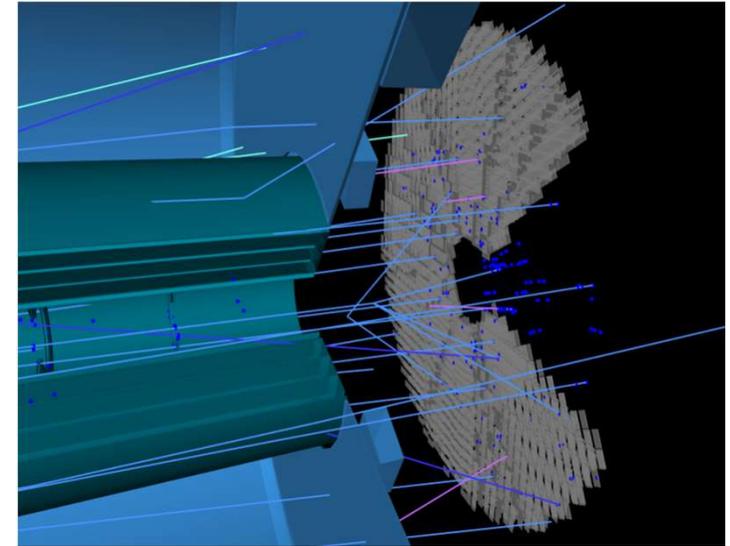

- Timing information helps in separating random geometrical overlaps if  $\sigma_t < 30 \text{ ps}$

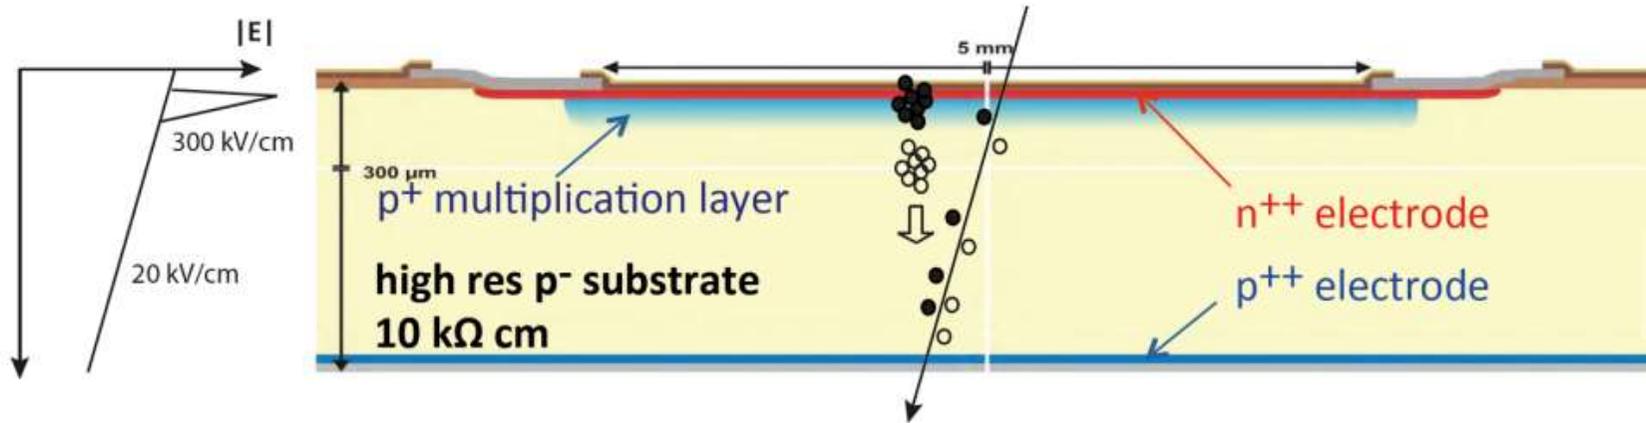

- At large  $|\eta|$  tracker resolution is worse than primary vertices separation
- Large contamination of tracks from pileup events:  
wrong computation of missing energy
- Timing separation allows to reduce contaminations at the same level as during Run-2
- CMS also explored impact on particle identification during heavy ion runs and detection of long-lived particles.

- Associate timing measurement to each reconstructed track.
- ATLAS: High Granularity Timing Detector (HGTD)
  - based on LGAD detectors
  - covering the region  $2.4 < |\eta| < 4$
- CMS: MIP Timing Detector (MTD)
  - LGAD detectors in the forward region  $1.6 < |\eta| < 3$
  - Scintillators (LYSO+SiPM) layer in the barrel  $|\eta| < 1.45$

# Low Gain Avalanche Diodes

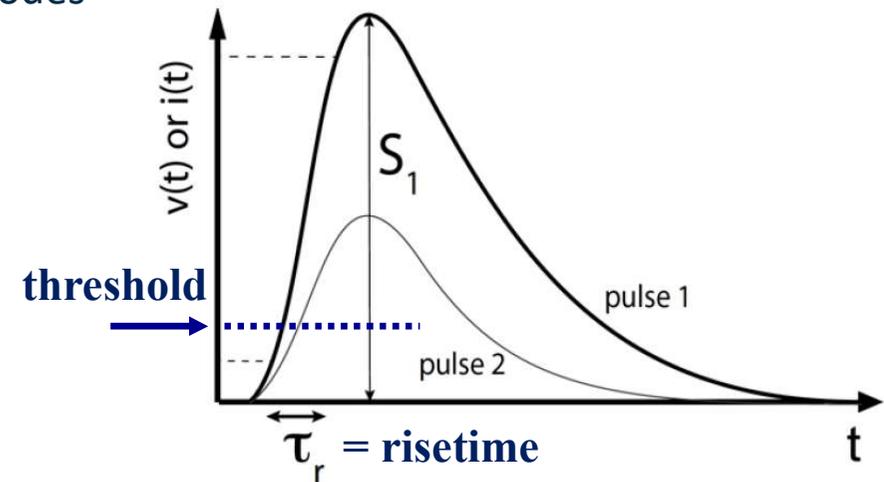

- Silicon detector with internal gain
- Arrival time defined as the time of crossing a predefined threshold
- Planar geometry to reduce arrival time fluctuations and distorted electric field
- granularity limited by cross-talk between nearby electrodes

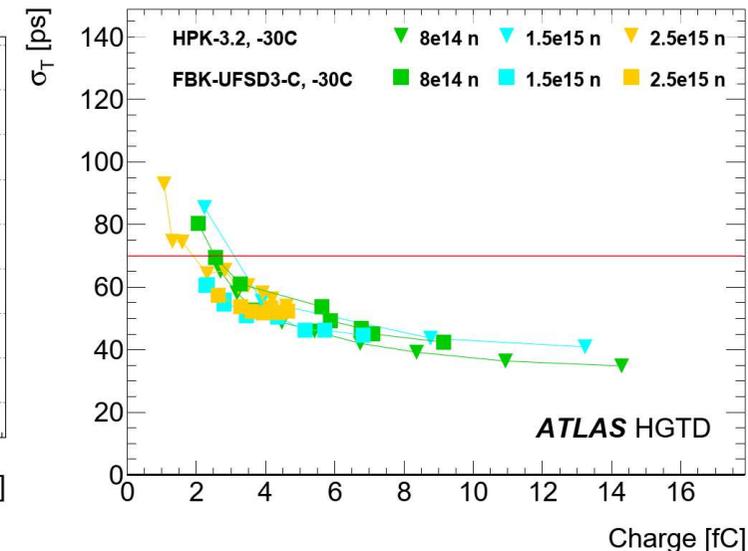

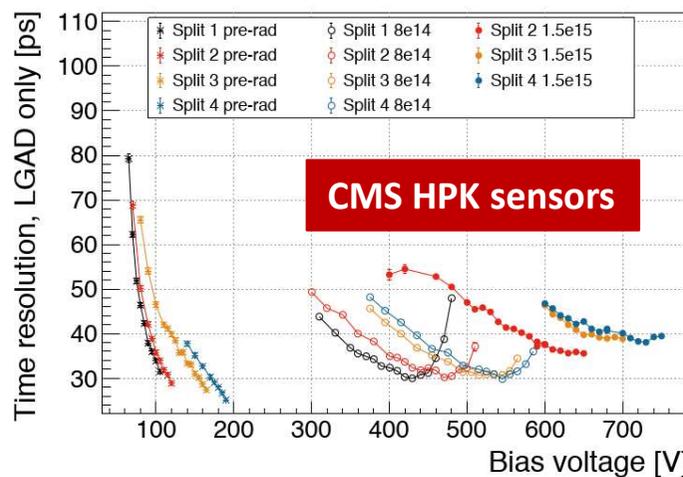

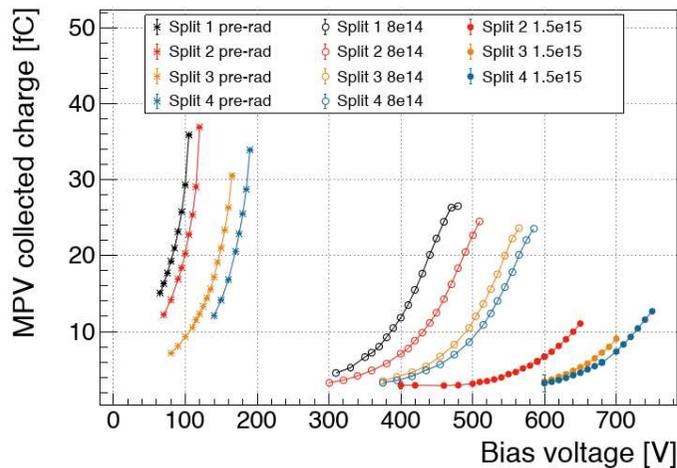

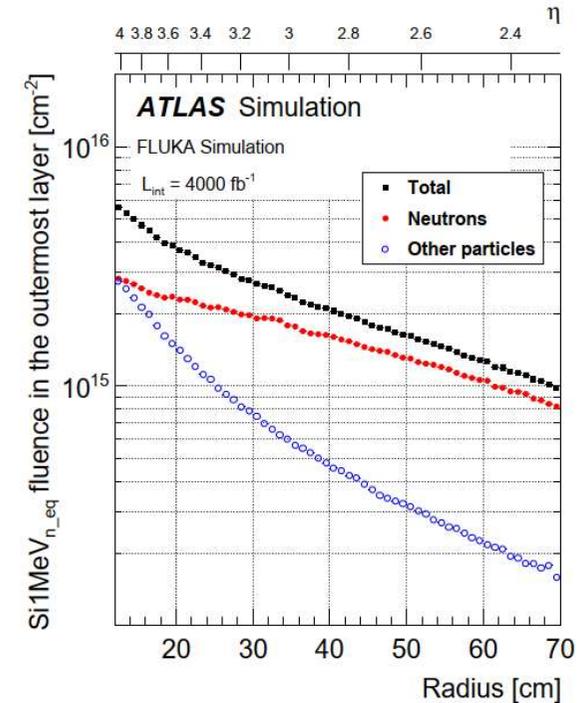

$$\sigma_t^2 = \underbrace{\left( \frac{V_{th}}{dV/dt} \Big|_{rms} \right)^2}_{\sigma_{\text{time walk}}^2} + \underbrace{\left( \frac{\text{Noise}}{dV/dt} \right)^2}_{\sigma_{\text{noise}}^2} + \sigma_{\text{arrival}}^2 + \sigma_{\text{dist}}^2 + \sigma_{\text{TDC}}^2$$

$\frac{dV}{dt} \sim \frac{V_{\text{picco}}}{\tau_r}$

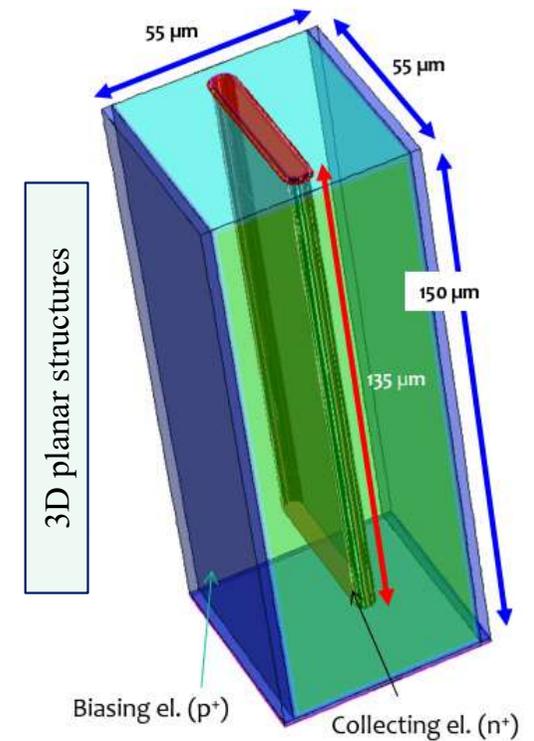

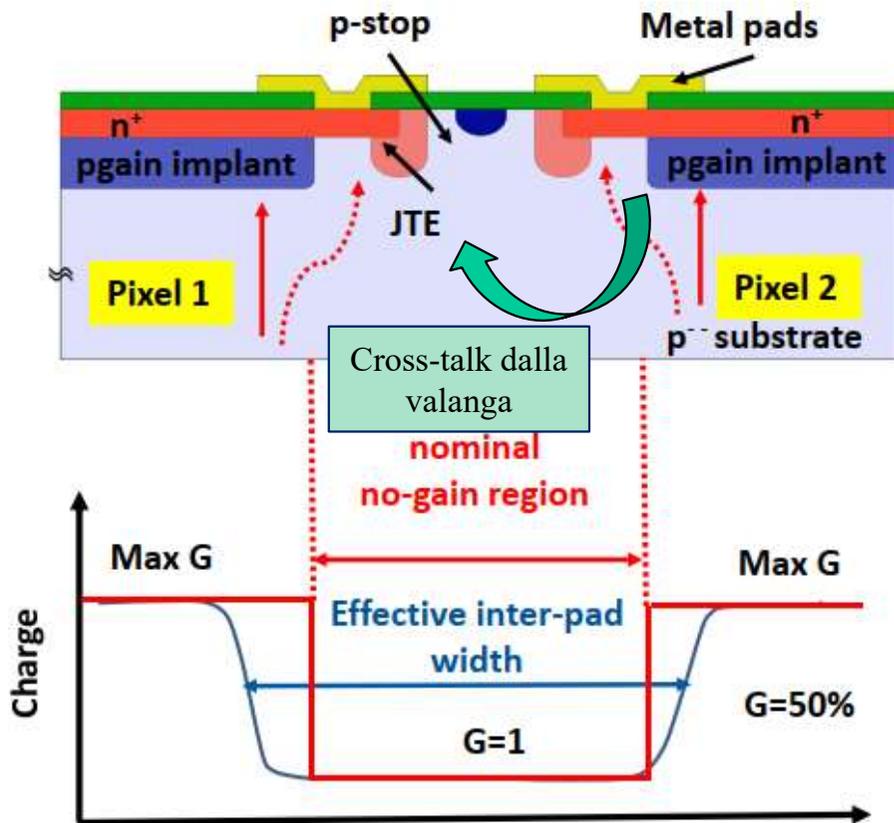

arrival fluct.      distortion low w-field

- Radiation damage may cause loss of signal:
  - trapping of primary ionization
  - smearing of the highly doped multiplication region
- In the current prototyping phase detectors seem to maintain adequate timing resolution.
- Possible mitigation is replacement of most irradiated sensors (HGTD) and multiple measurements to reduce uncertainties

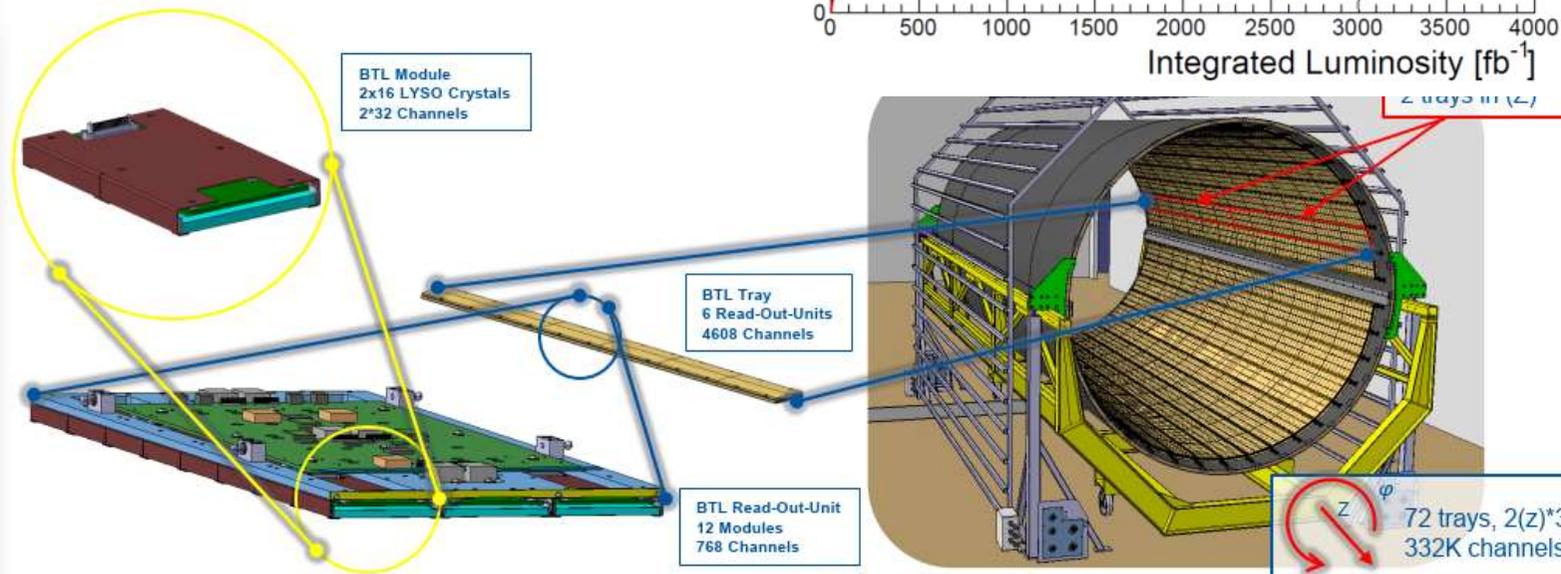

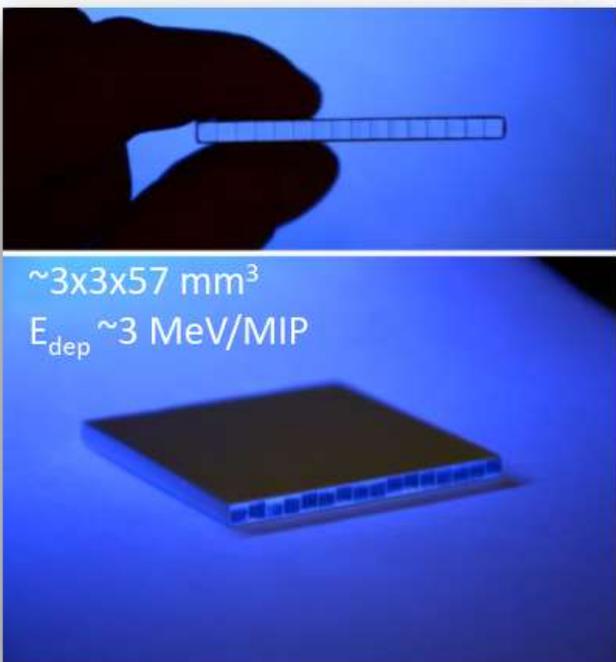

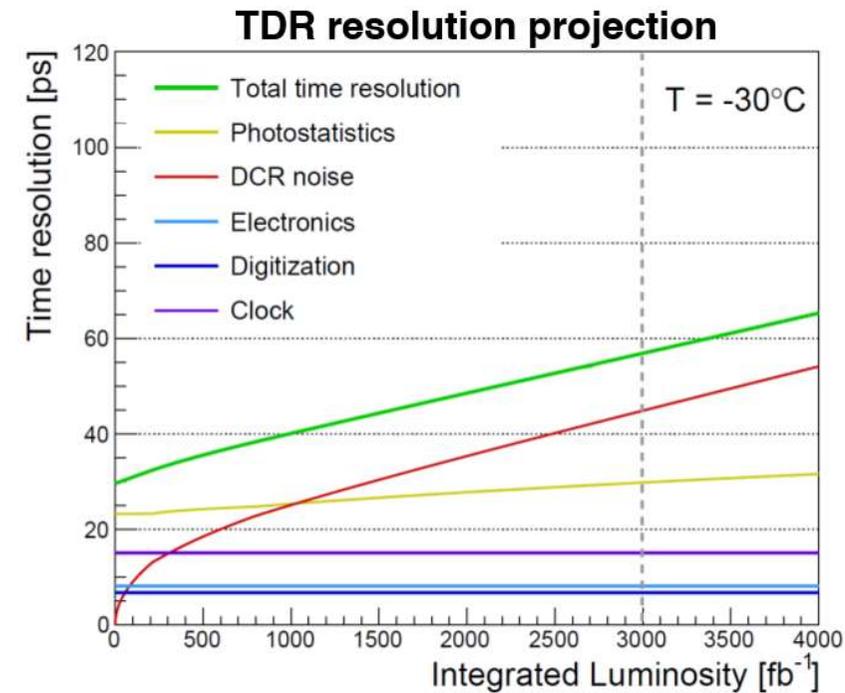

- Main limitation of current LGADs is the segmentation:
  - 1.3 mm x 1.3 mm for both HGTD and MTD:
  - dead regions to avoid afterpulsing in nearby channels
  - different ideas being working out in order to go towards a full 4D-sensor

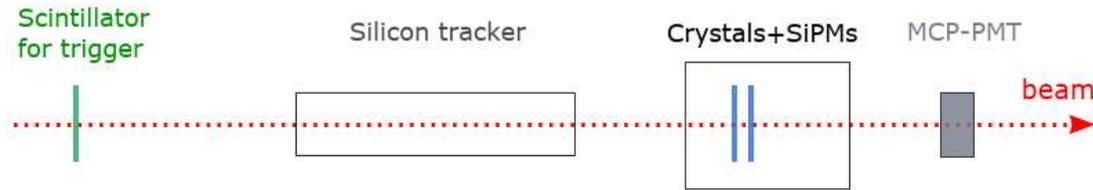

# MTD: Barrel Timing Layer

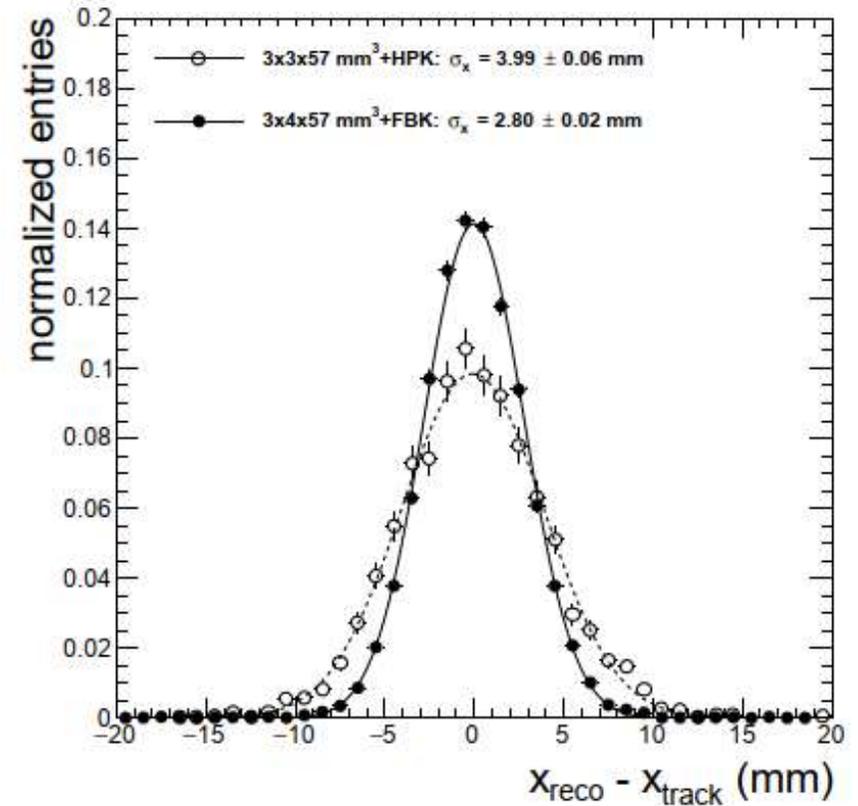

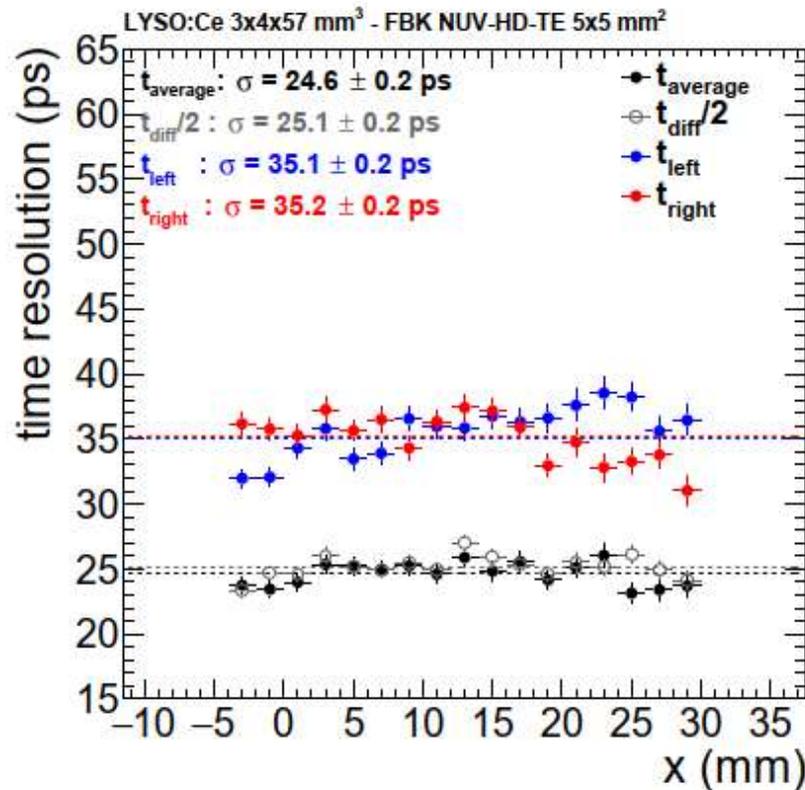

- Main constraint for the barrel layer is to fit in the 40 mm gap between the CMS tracker and ECAL
- LYSO crystal bars 3x3x57 mm
- read at both ends by SiPM
- Radiation effect in the Dark Count Rate of the SiPM
- Important thermal management to keep the detector at low temperature / noise suppression in the front-end chip

- Recent test beam results

- Time resolution from average of both ends SiPM 25 ns
- spatial resolution along the bar, from time difference, 3 mm

**Testbeam results**

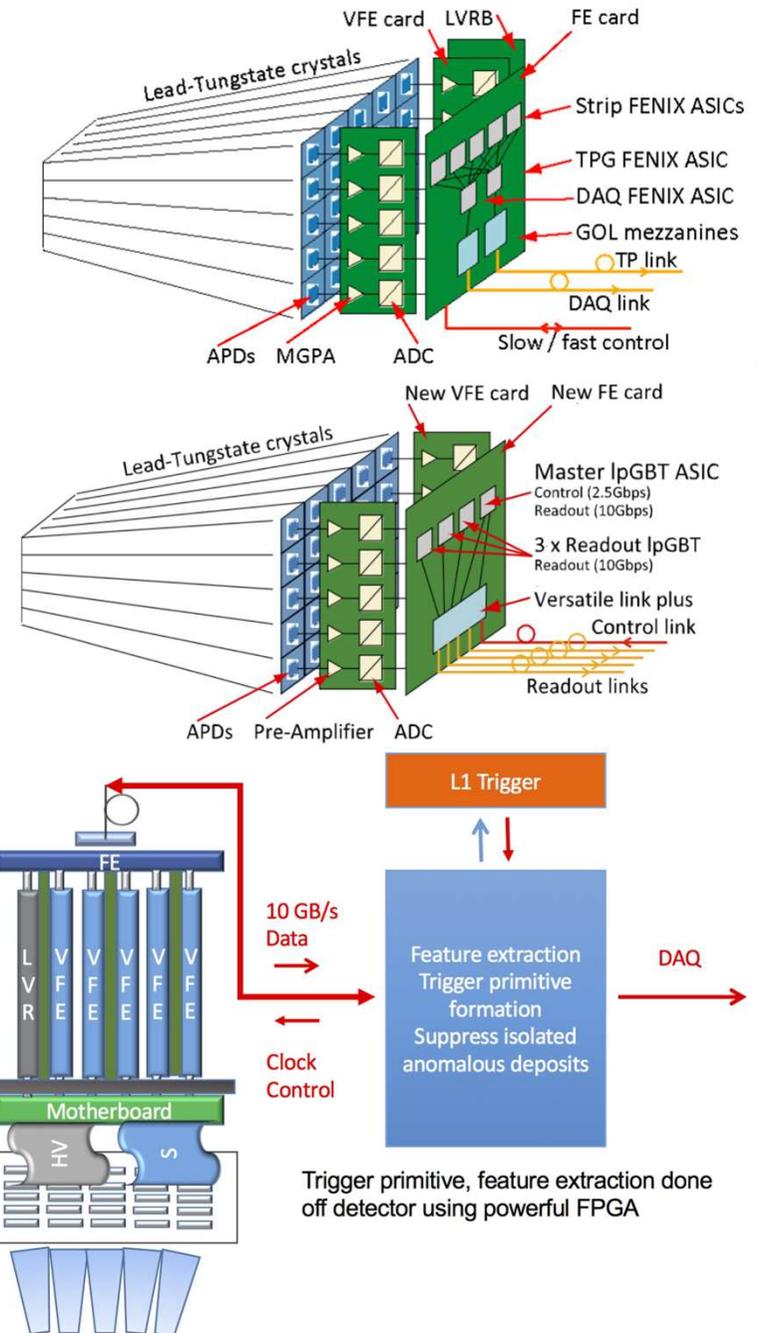

$$\left(\frac{\sigma}{E}\right)^2 = \left(\frac{2.8\%}{\sqrt{E}}\right)^2 + \left(\frac{0.12}{E}\right)^2 + (0.30\%)^2$$

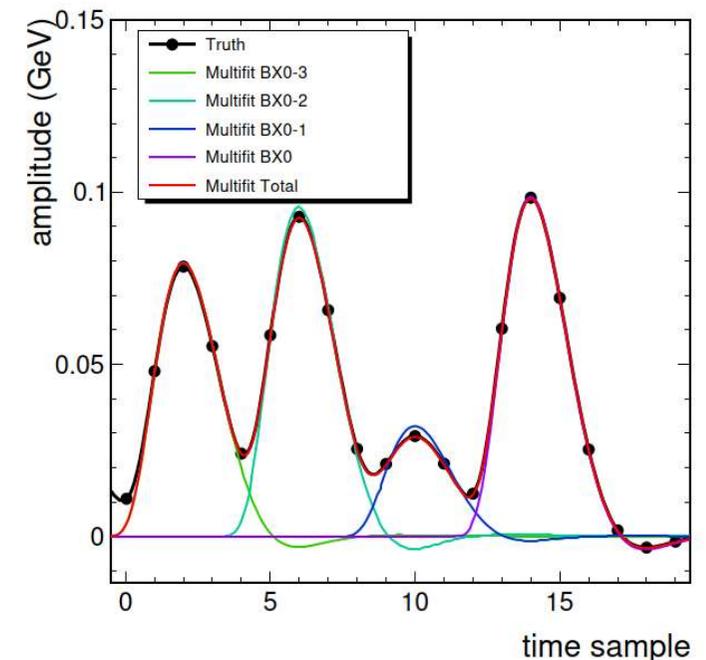

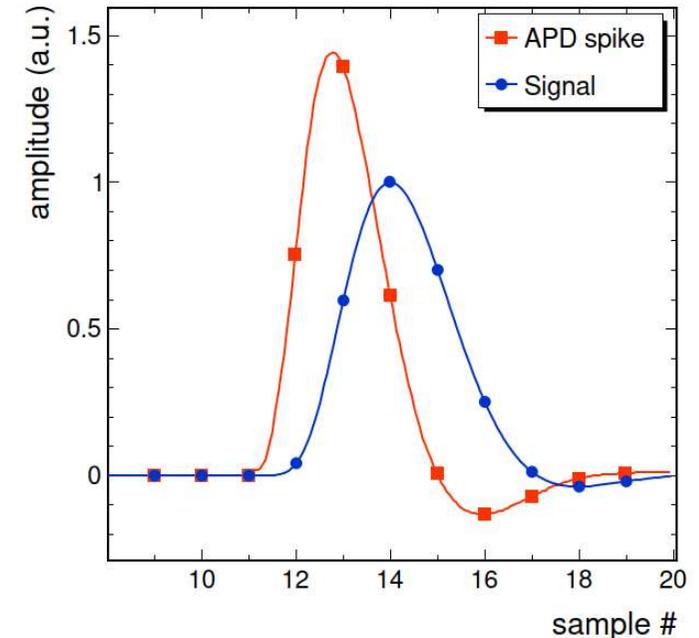

- **PbWO4 crystals**
  - Creation of color centers due to atomic displacement in the crystal
  - Shift of the absorption edge, overlapping with the peak of photon emission spectrum
  - Reduced transmission in the material
  - Light output at and of Phase2 reduced to 25–40%, depending on  $\eta$
- **APD**
  - Main effect is the displacement damage in the silicon bulk
  - Causing increase in dark current  $I_{\text{Dark}}$
  - Noise term if proportional to  $\sqrt{I_{\text{Dark}}}$
  - A factor 10 increase on noise term ( $\sim 1 \text{ GeV at } 3000 \text{ fb}^{-1}$ )
- **Mitigation**
  - Operation at lower temperature
  - $I_{\text{Dark}}$  reduces by about a factor 2 every  $8 \text{ }^\circ\text{C}$

- Cannot change the detector, so upgrade the readout electronics
- Front-end
  - Effect of pileup signals from nearby bunches
  - Increase in dark current  $I_{\text{Dark}}$  due to radiation damage
  - Both contribution reduced by fast shaping time
  - **Trans Impedance Amplifier**
  - **Sampling at 160 MHz**
- L1 Trigger signal
  - Current detector integrates the signals of a 5x5 crystals towers
    - cannot apply isolation cuts
  - Includes an on chip suppression of spikes
    - large signals in individual APD
    - due to hadronic interactions in the sensor
  - **move full data of each crystal off-detector**
  - **perform pulse shape analysis and trigger algorithm** (isolation, spike rejection) **on FPGA**

- Cannot change the detector, so upgrade the readout electronics

    - due to hadronic interactions in the sensor
  - **move full data of each crystal off-detector**
  - **perform pulse shape analysis and trigger algorithm** (isolation, spike rejection) **on FPGA**

- **Sampling calorimeter**

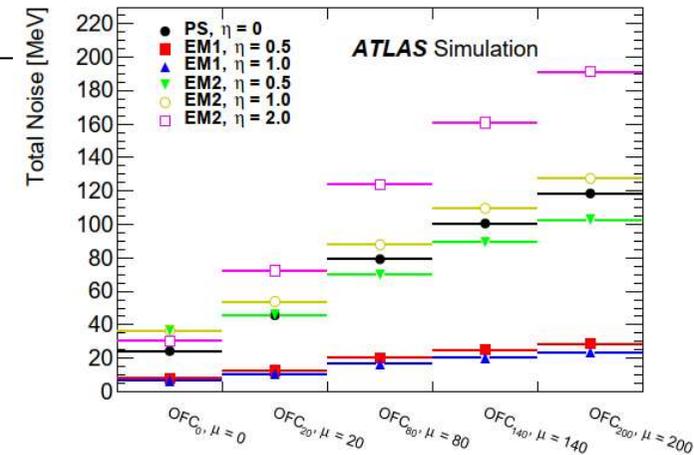

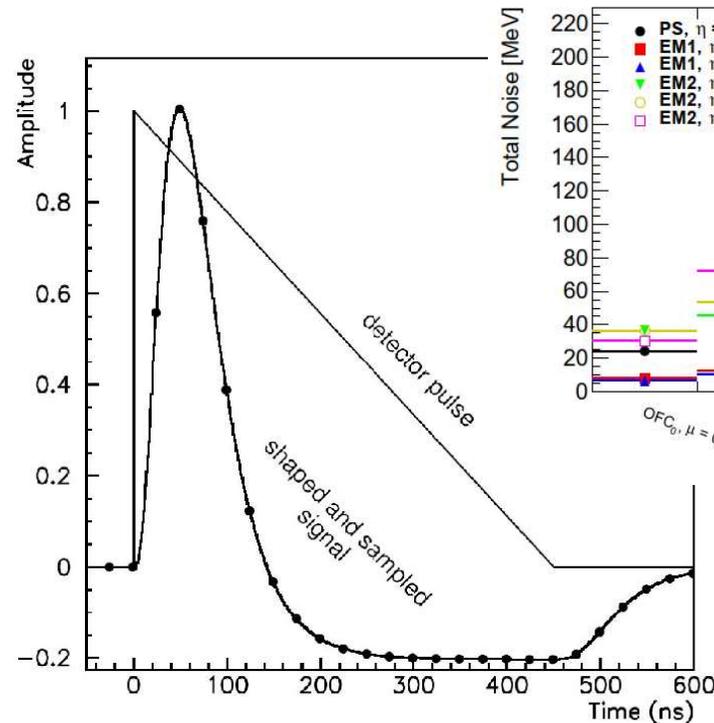

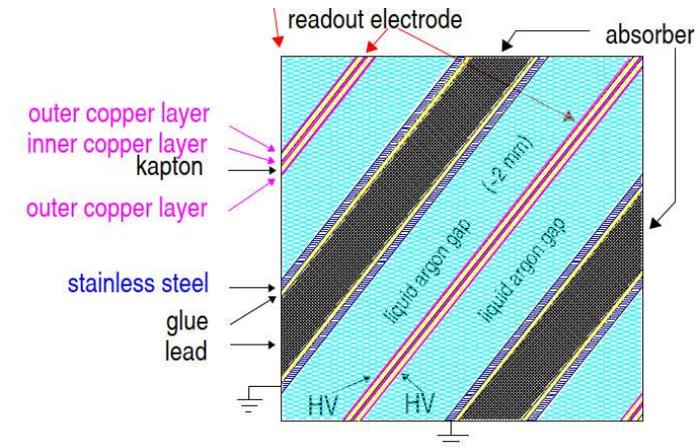

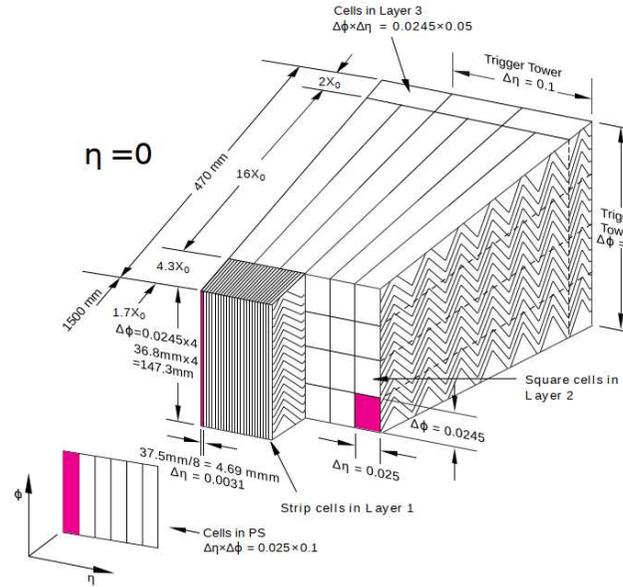

- Pb absorber
- LAr active ~2 mm gap
- Segmented Cu electrode
- Reduced sensitivity to irradiation

- Lateral and **longitudinal** segmentation

- $\pi^0$  identification by  $\gamma$  separation at the beginning of the shower
- direction measurement
- leakage corrections

- **Readout electronics**

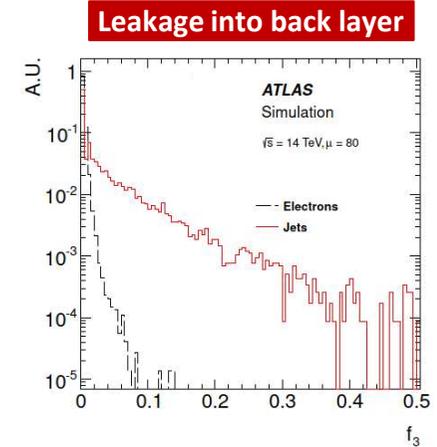

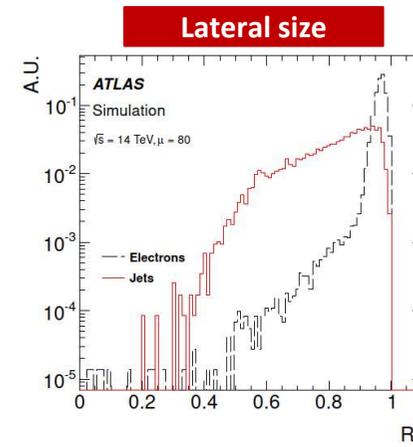

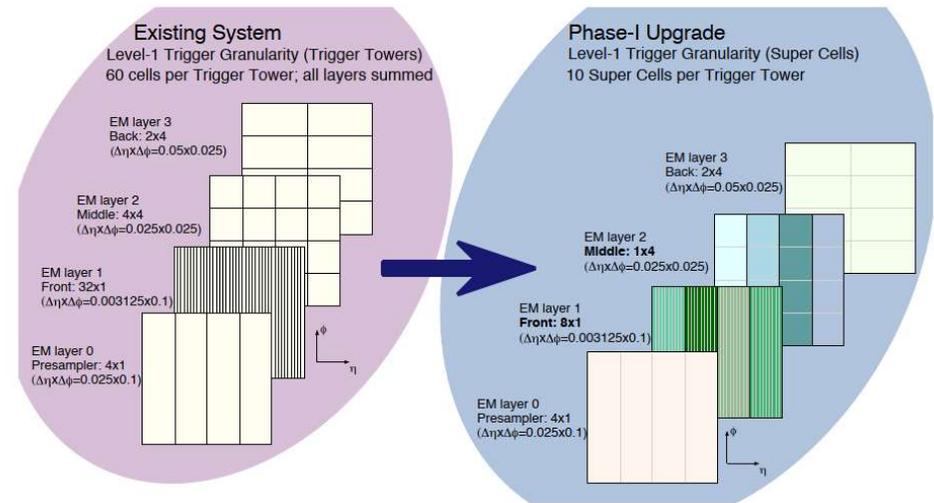

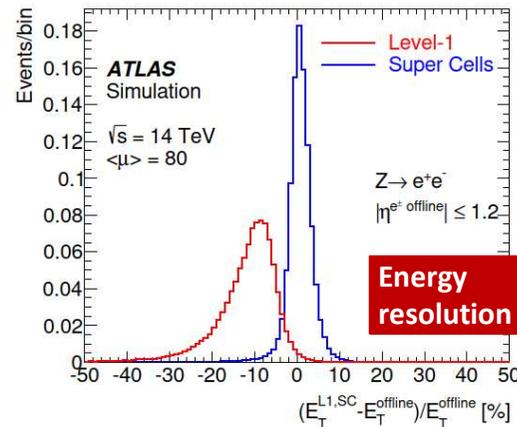

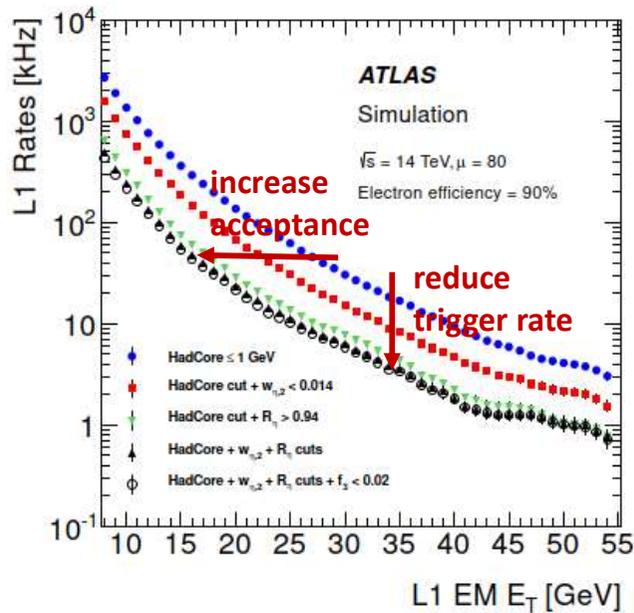

- CR-(RC)<sup>2</sup> bipolar shaping to reduce pileup effects
- Optimal performance at  $\tau_{\text{shaper}} = 13$  ns
- 40 MHz sampling
- Optimal filtering for energy measurement
- **Update FE and readout system and L1 trigger improvements**

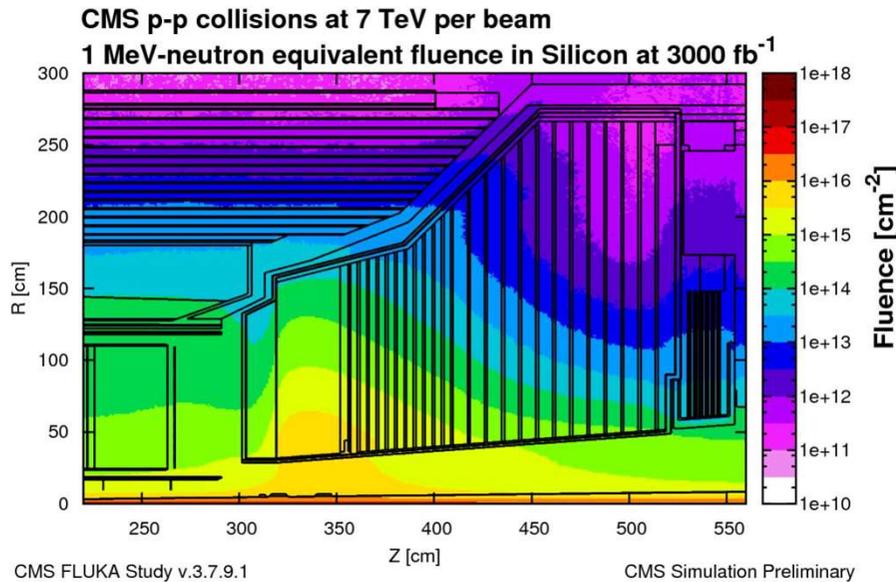

## L1 Trigger

- L1 trigger had access only to total energy in a tower
- $\Delta\eta \times \Delta\phi = 0.1 \times 0.1$
- During LS2 upgraded to provide more granular Super Cell output
- improved energy determination and shower shape variables

Layer	Elementary Cell	Trigger Tower		Super Cell	
		$\Delta\eta \times \Delta\phi$	$n_\eta \times n_\phi$	$\Delta\eta \times \Delta\phi$	$n_\eta \times n_\phi$
0	Presampler	$0.025 \times 0.1$	$4 \times 1$	$0.1 \times 0.1$	$4 \times 1$
1	Front	$0.003125 \times 0.1$	$32 \times 1$	$0.1 \times 0.1$	$8 \times 1$
2	Middle	$0.025 \times 0.025$	$4 \times 4$		$1 \times 4$
3	Back	$0.05 \times 0.025$	$2 \times 4$	$2 \times 4$	$0.1 \times 0.1$

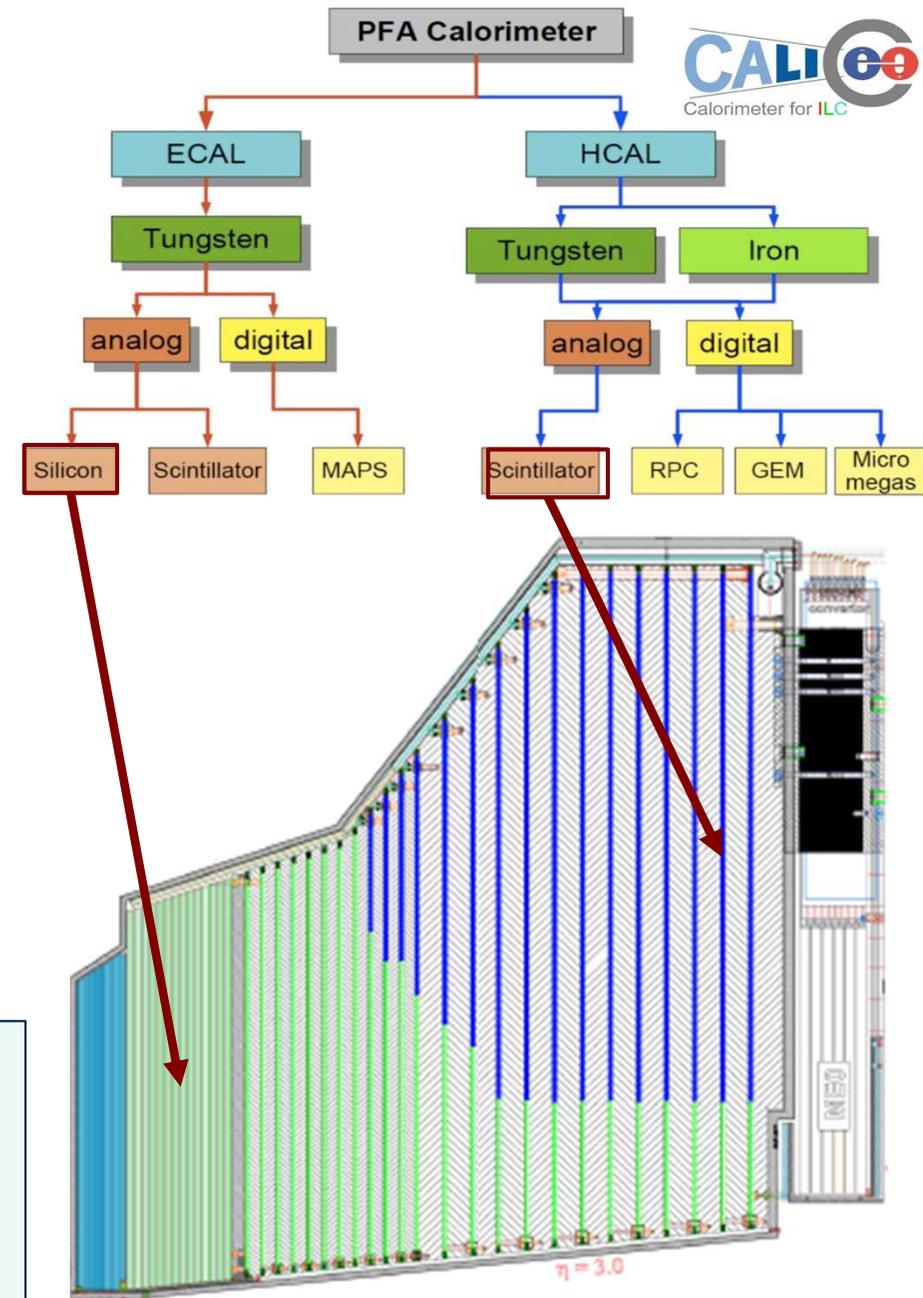

- Radiation damage in the forward calorimeter region much higher than in barrel
  - Same values as in the tracker region

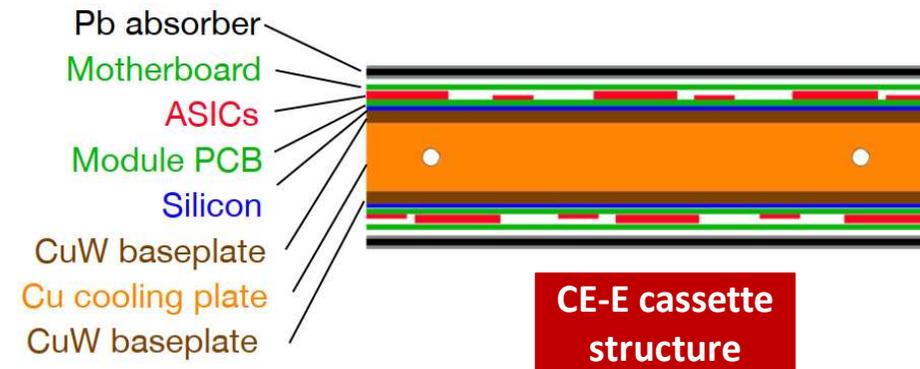

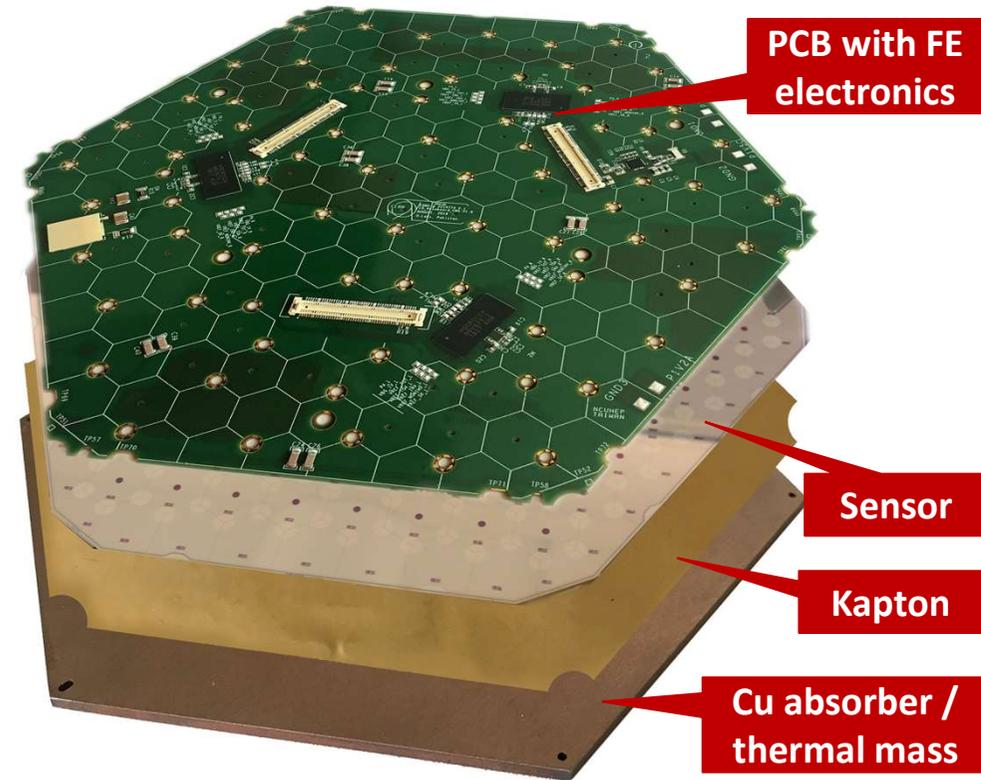

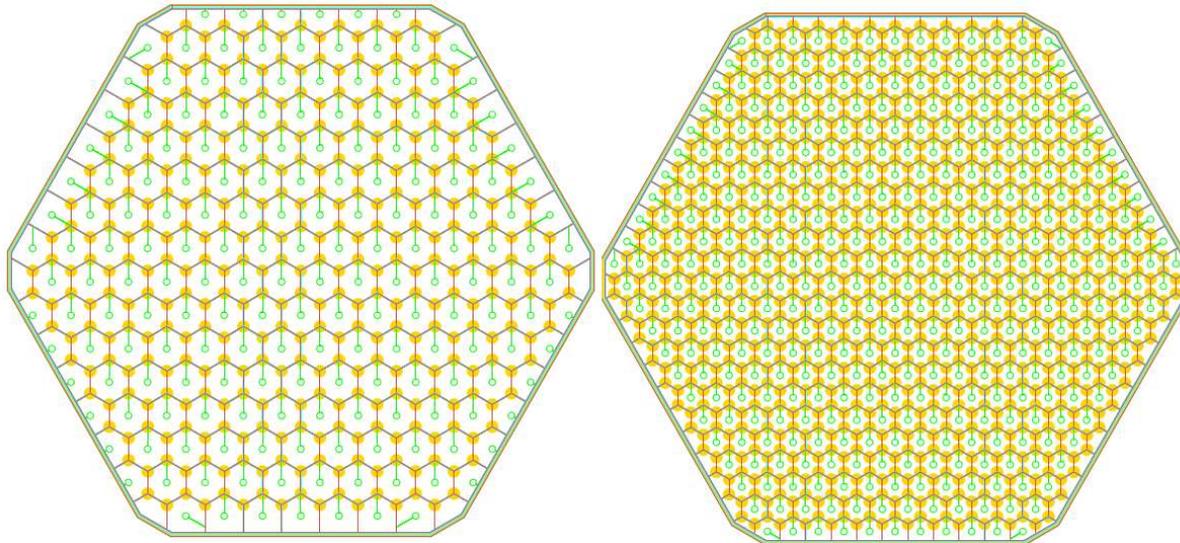

- $\text{PbWO}_4$  crystals will degrade excessively after  $500 \text{ pb}^{-1}$
- Complete replacement of endcap calorimetry:

- Electromagnetic section CE-E
  - **Silicon** + Cu, CuW, Pb, 26 layers,  $28 X_0$ ,  $\sim 1.5 \lambda$
- Hadronic section CE-E
  - **Scintillators** and **Silicon** + Steel, 7+14 layers,  $\sim 8.5 \lambda$
- Polytilene shield to reduce albedo neutrons into the tracker

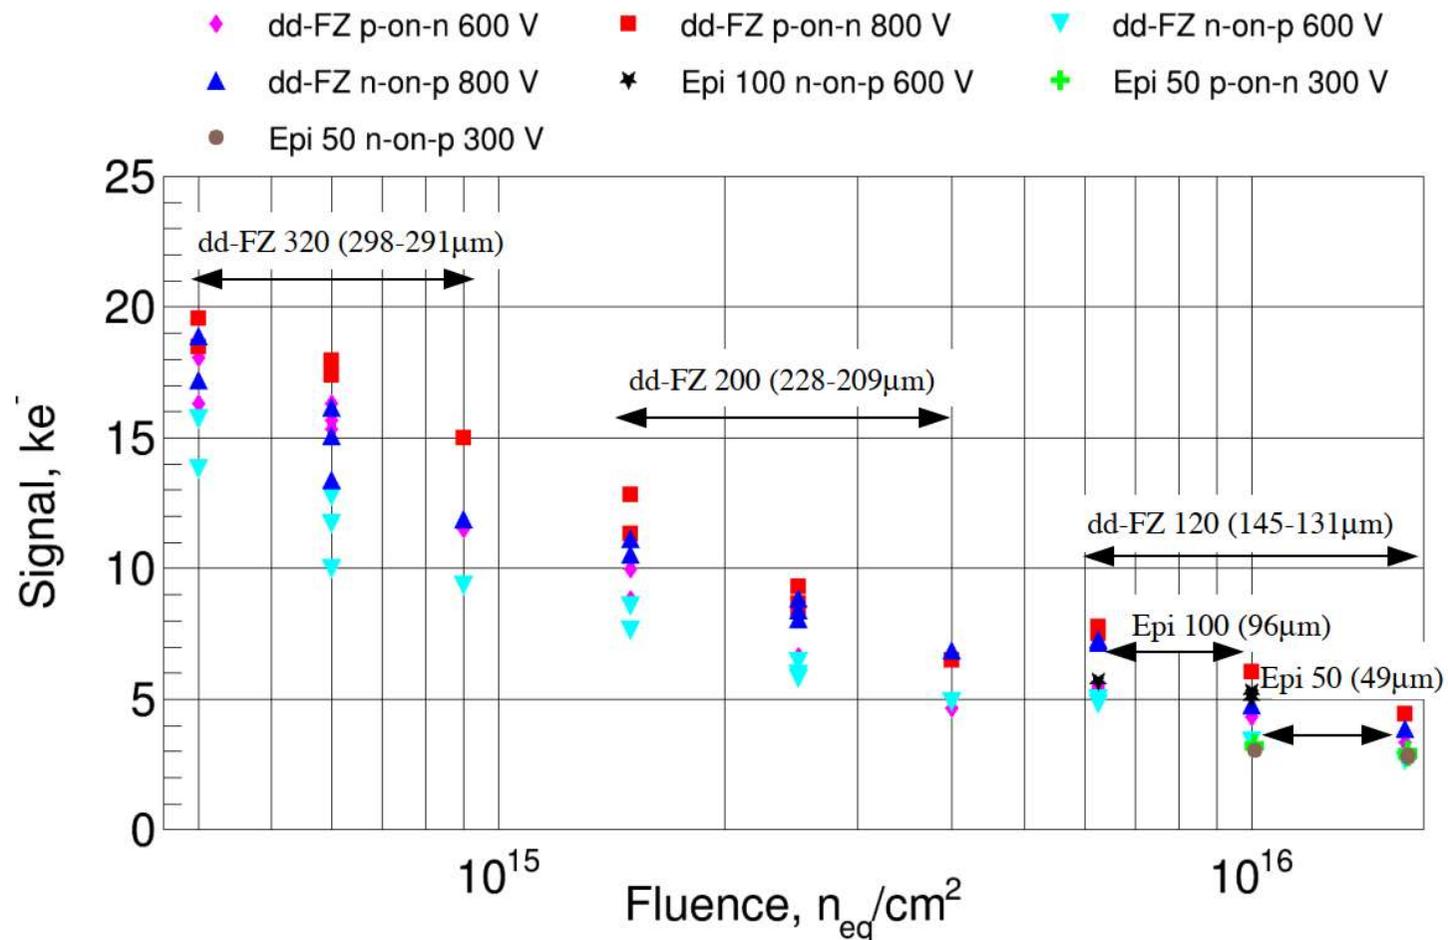

# The Silicon Module

- Total of 620 m<sup>2</sup> of silicon sensors
- Hexagonal tiles from 8" wafer
- Different sensors depending on radiation level:
  - 1.18 cm<sup>2</sup> cell on 300 μm substrate
  - 1.18 cm<sup>2</sup> cell on 200 μm substrate
  - 0.52 cm<sup>2</sup> cell on 120 μm substrate

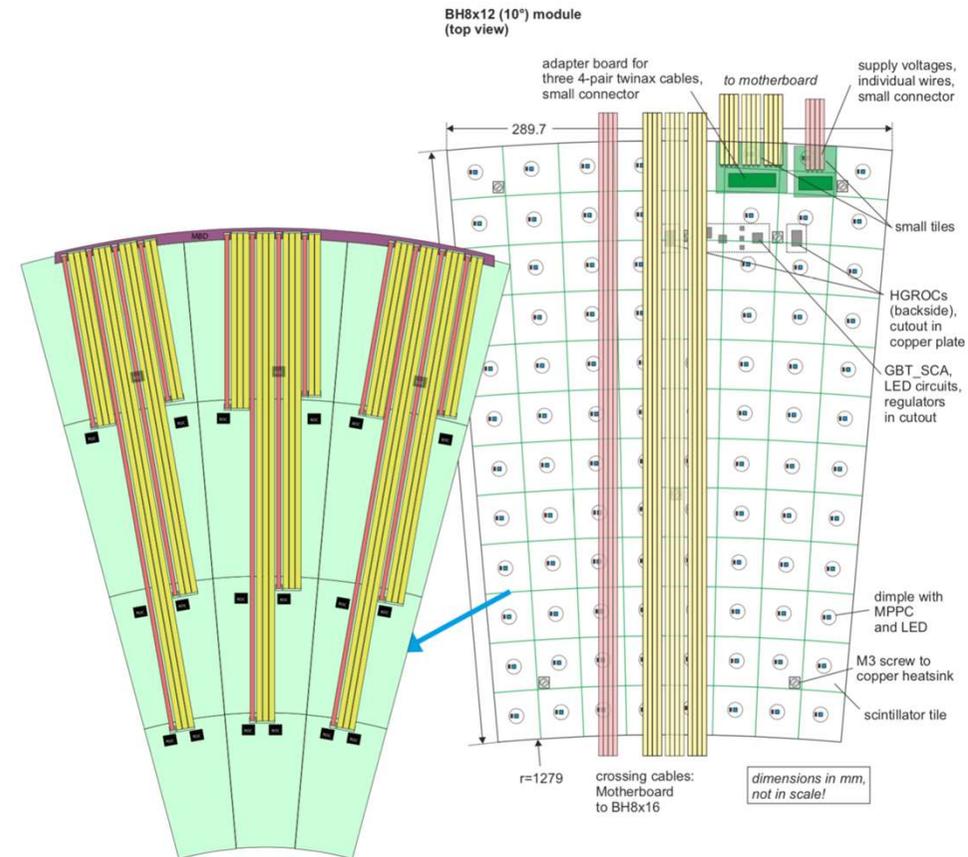

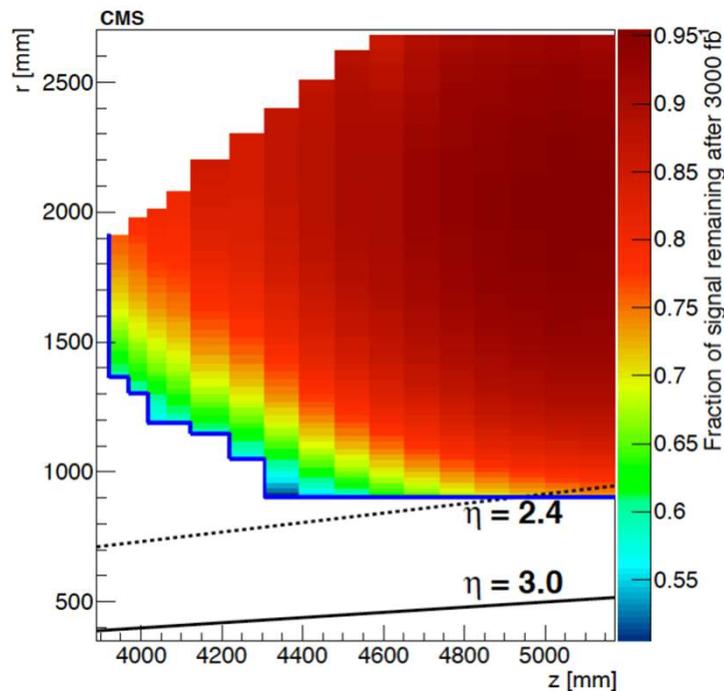

- Radiation level comparable with silicon tracker
- Thin sensors provides required radiation hardness
- Cell size adapted to maintain sufficiently low sensor capacitance (<65 pF)
- Operation at  $-30\text{ }^{\circ}\text{C}$  to reduce leakage current

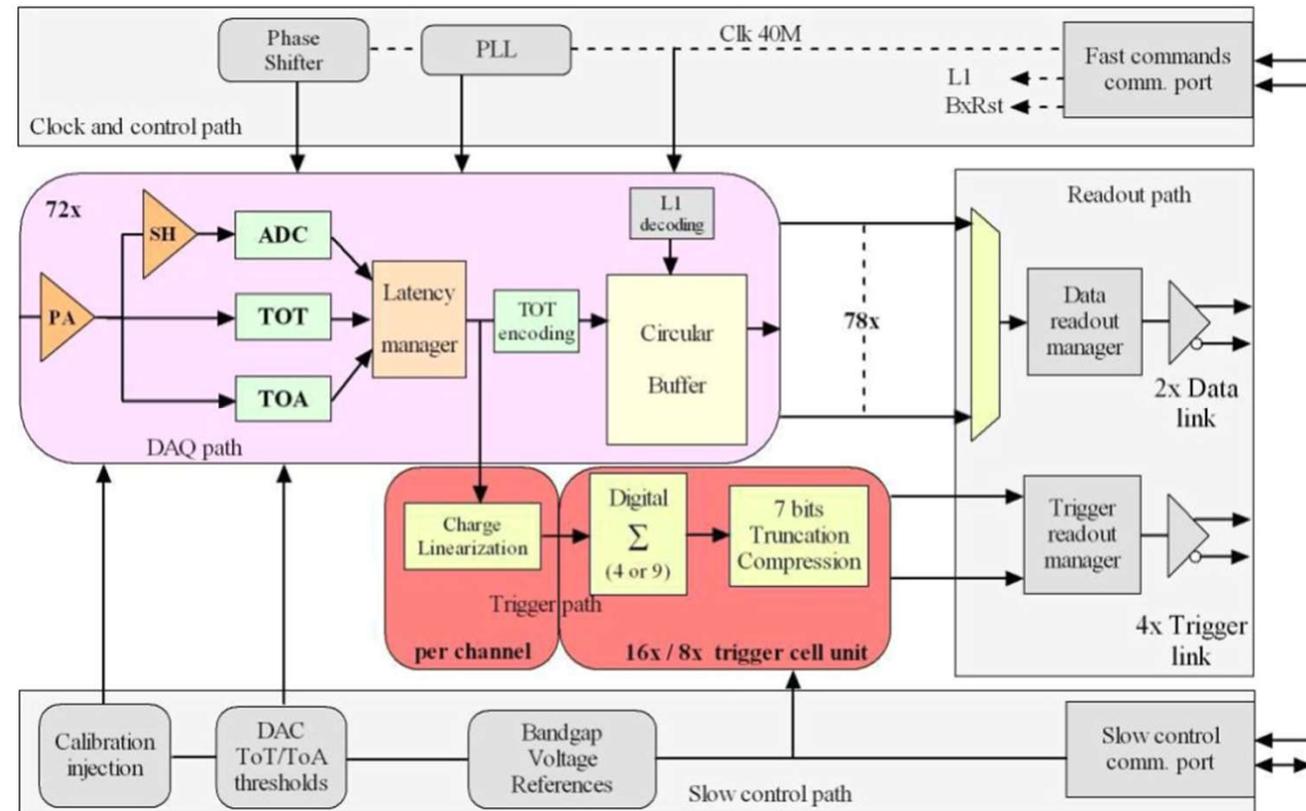

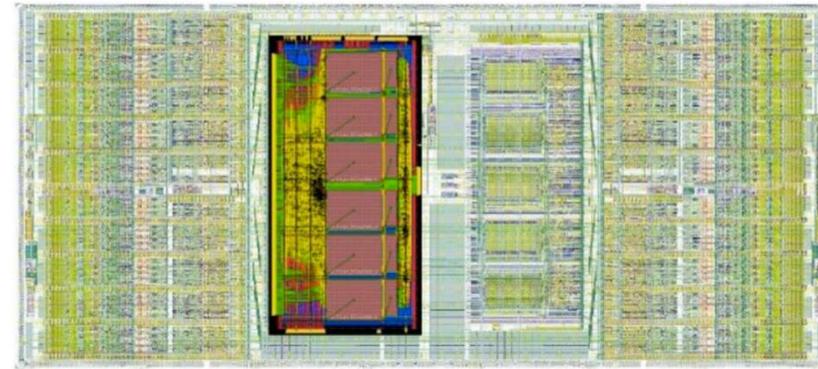

# Scintillator modules

- Total of 320 m<sup>2</sup> of silicon sensors
- 3 mm thick scintillator tiles ranging from 2 × 2 cm<sup>2</sup> to 5.5 × 5.5 cm<sup>2</sup> area
- 2 mm<sup>2</sup> SiPM-on-tile readout
- Cooling at -30 °C helps in keeping low dark rate even after radiation damage
- MIP's S/N > 5 for the whole detector lifetime

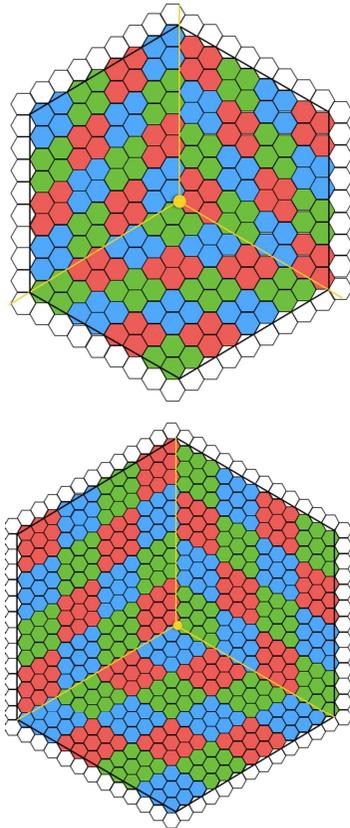

## HGROC3 characteristics

- Same readout chip for Si and SiPM readout
- 72 channels
- <20 mW power
- Radiation tolerant: 2 MGy and  $1 \times 10^{16} n_{eq}/cm^2$
- ENC < 2500 e with 65 pF load
- Timing resolution of 10s ps
- On chip zero suppression
- Fixed latency path for sum of trigger cells

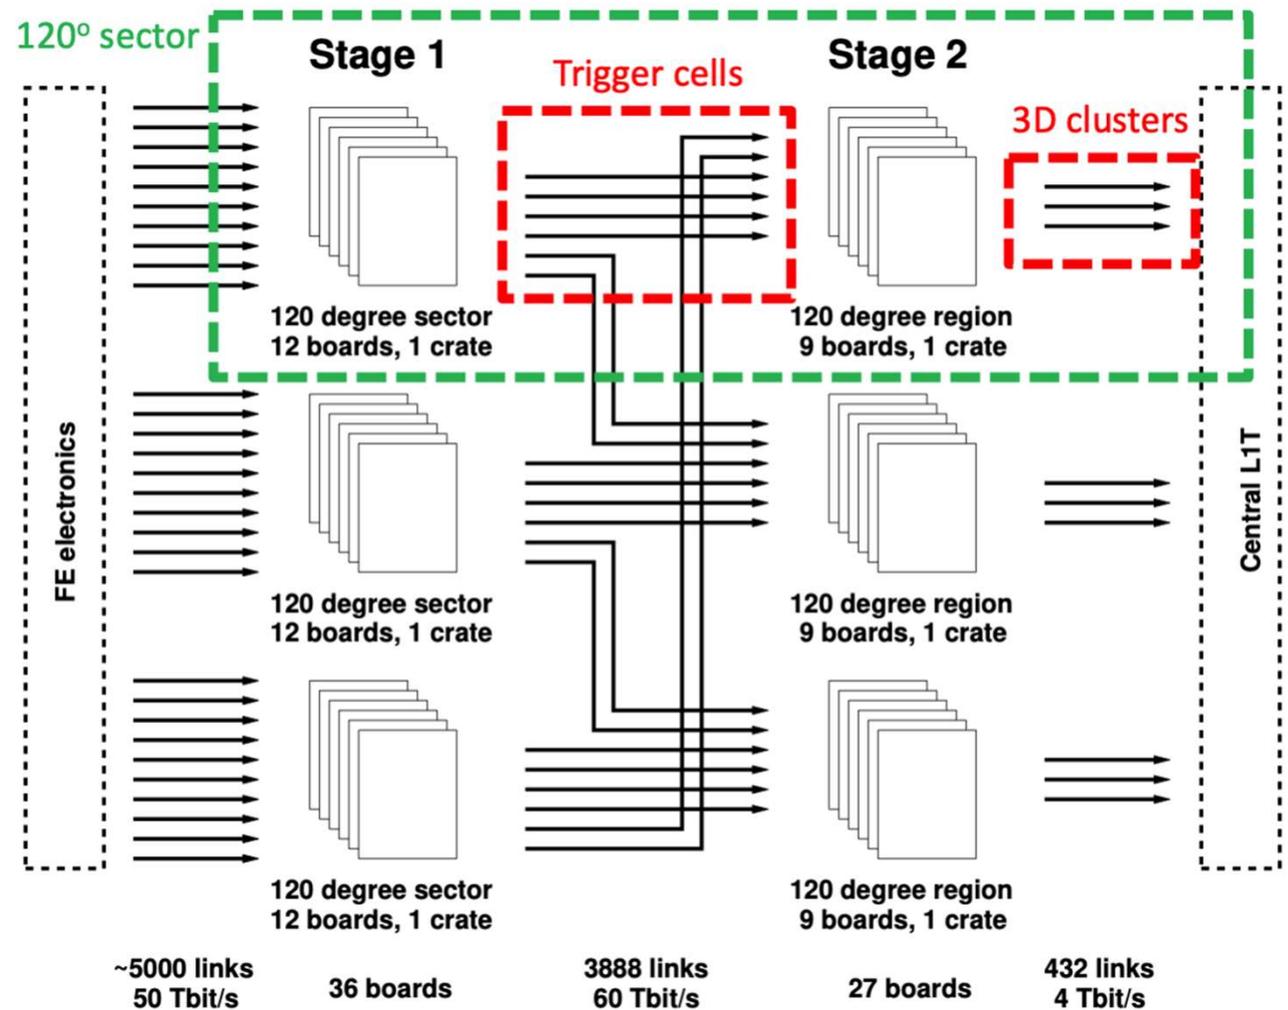

## On detector

- zero suppression
- analog sum
- Latency 1.5  $\mu\text{s}$

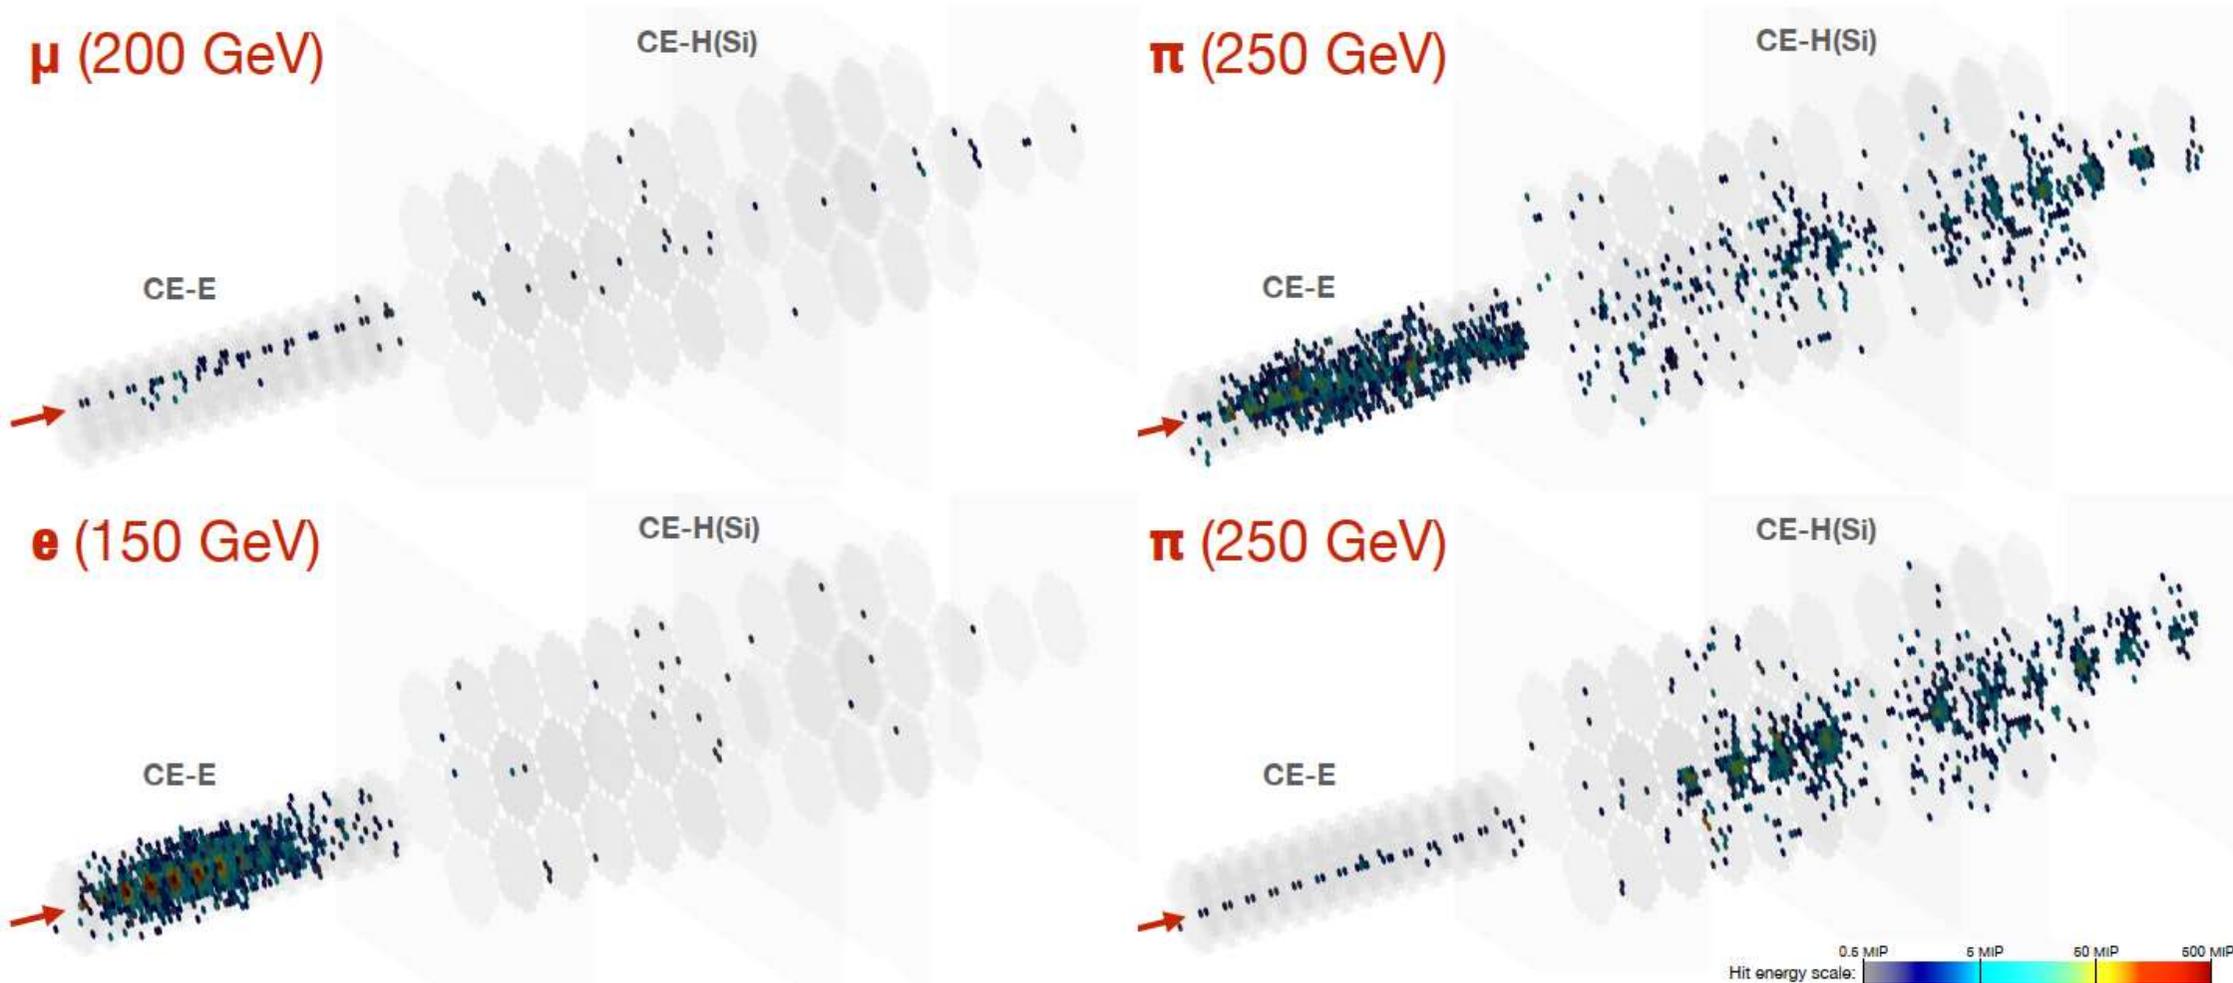

## Off detector

- 3D clustering
- $\eta$ - $\phi$  energy map
- Latency 3.5  $\mu\text{s}$

# MUON SYSTEM

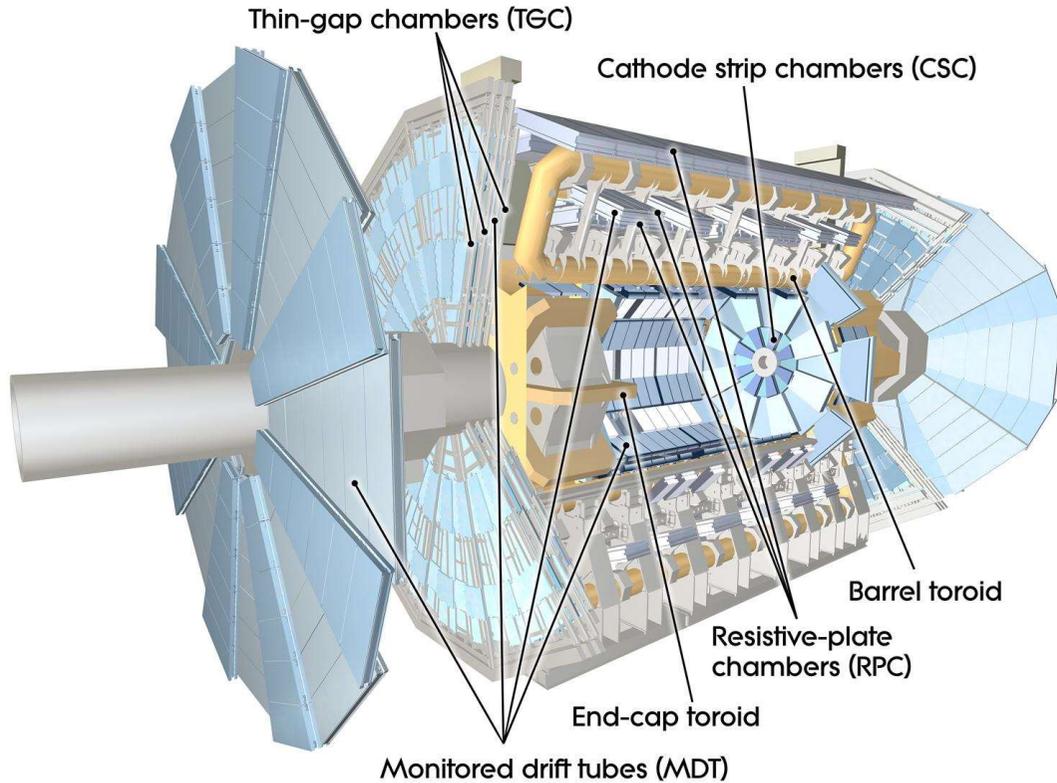

Istituto Nazionale di Fisica Nucleare

**Sezione di Milano**

**UNIVERSITÀ DEGLI STUDI DI MILANO**  
DIPARTIMENTO DI FISICA

## Trigger

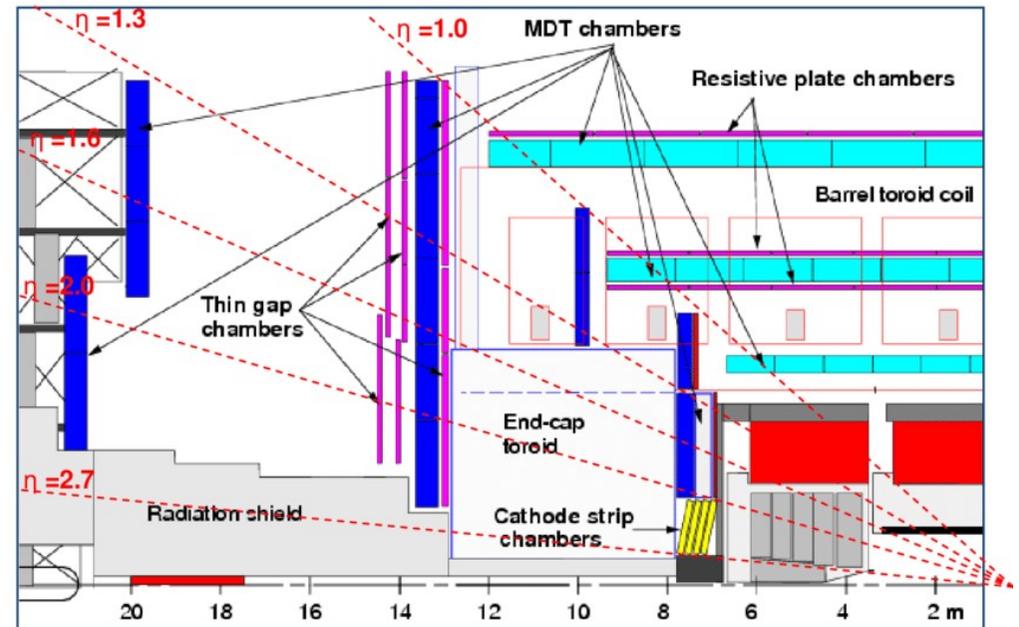

- RPC (Resistive Plate Chambers)
- TGC (Thin gap chambers)
- Fast signal (short drift distance)
- Measurement on the perpendicular coordinate.

The Muon System has two functions:

- different detector technologies

## Precision Tracking

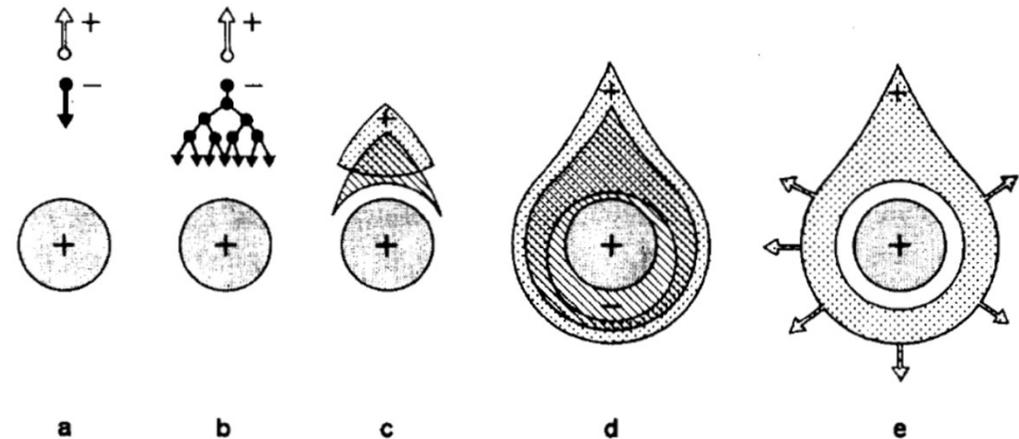

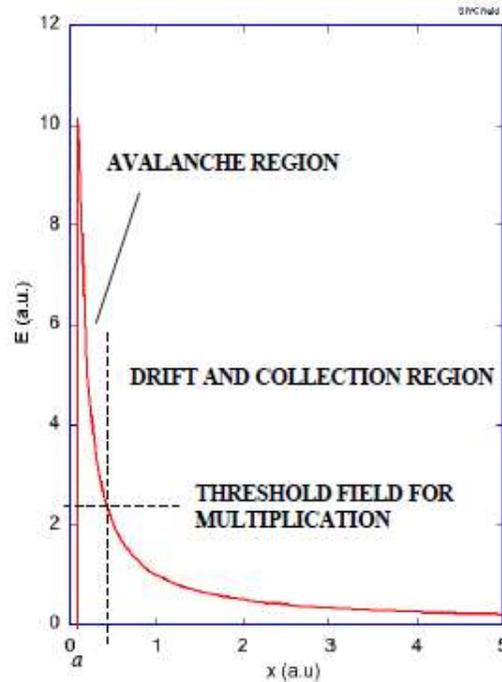

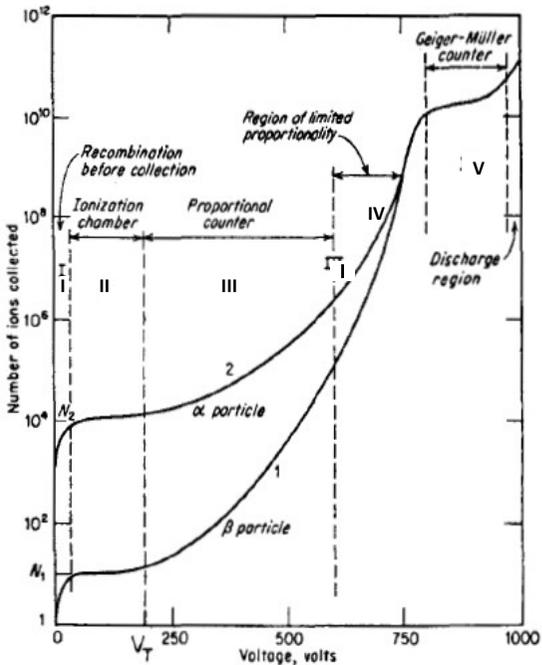

- MDT (Monitored Drift Tubes)
- CSC (Cathode Strip Chambers)
- Precision measurements on the bending plane for momentum determination
- Measurement of drift time

## Keywords to remember

- Primary ionization tens of e-/cm
- Electron drift velocity O(cm/μs)
- Multiplication in high electric field near the collecting electrode
- Space charge of positive ions distorts the electric field

Gas	Density, mg cm <sup>-3</sup>	$E_x$ eV	$E_I$ eV	$W_I$ eV	$dE/dx _{min}$ keV cm <sup>-1</sup>	$N_P$ cm <sup>-1</sup>	$N_T$ cm <sup>-1</sup>
Ne	0.839	16.7	21.6	30	1.45	13	50
Ar	1.66	11.6	15.7	25	2.53	25	106
Xe	5.495	8.4	12.1	22	6.87	41	312
CH <sub>4</sub>	0.667	8.8	12.6	30	1.61	37	54
C <sub>2</sub> H <sub>6</sub>	1.26	8.2	11.5	26	2.91	48	112
iC <sub>4</sub> H <sub>10</sub>	2.49	6.5	10.6	26	5.67	90	220
CO <sub>2</sub>	1.84	7.0	13.8	34	3.35	35	100
CF <sub>4</sub>	3.78	10.0	16.0	54	6.38	63	120

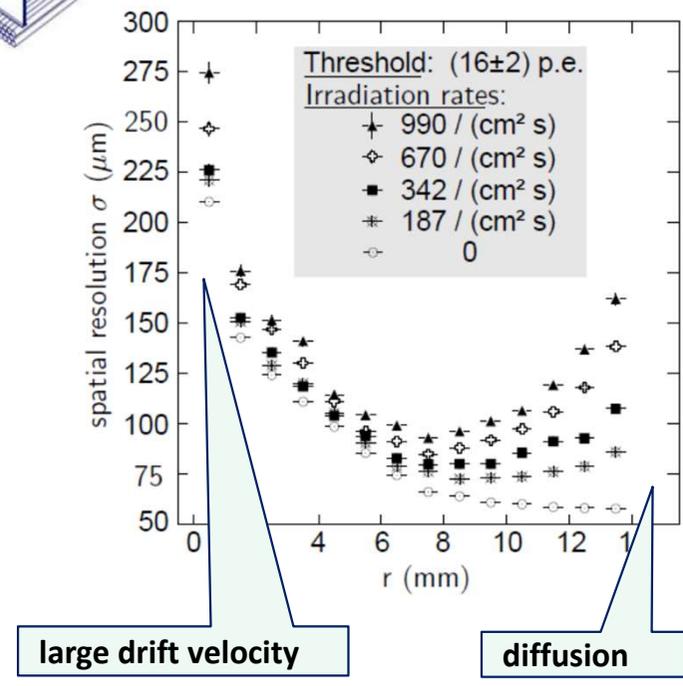

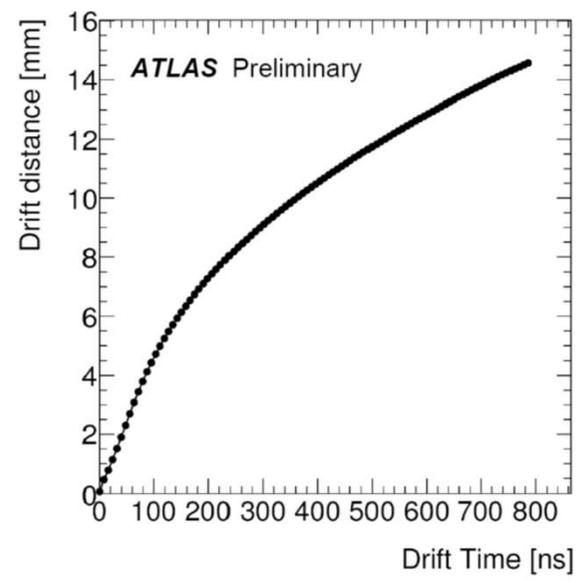

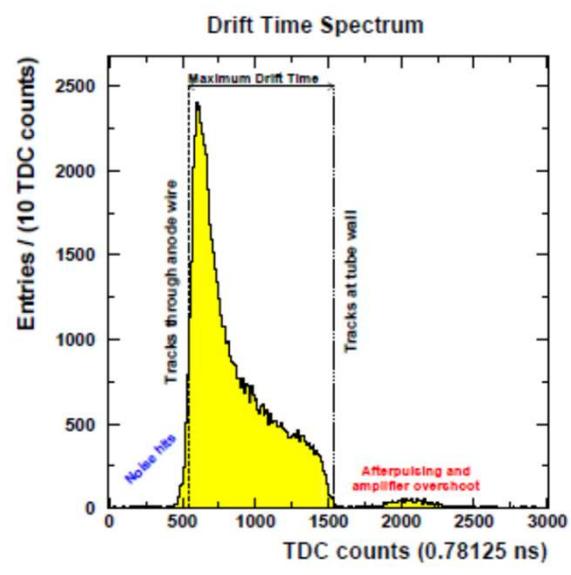

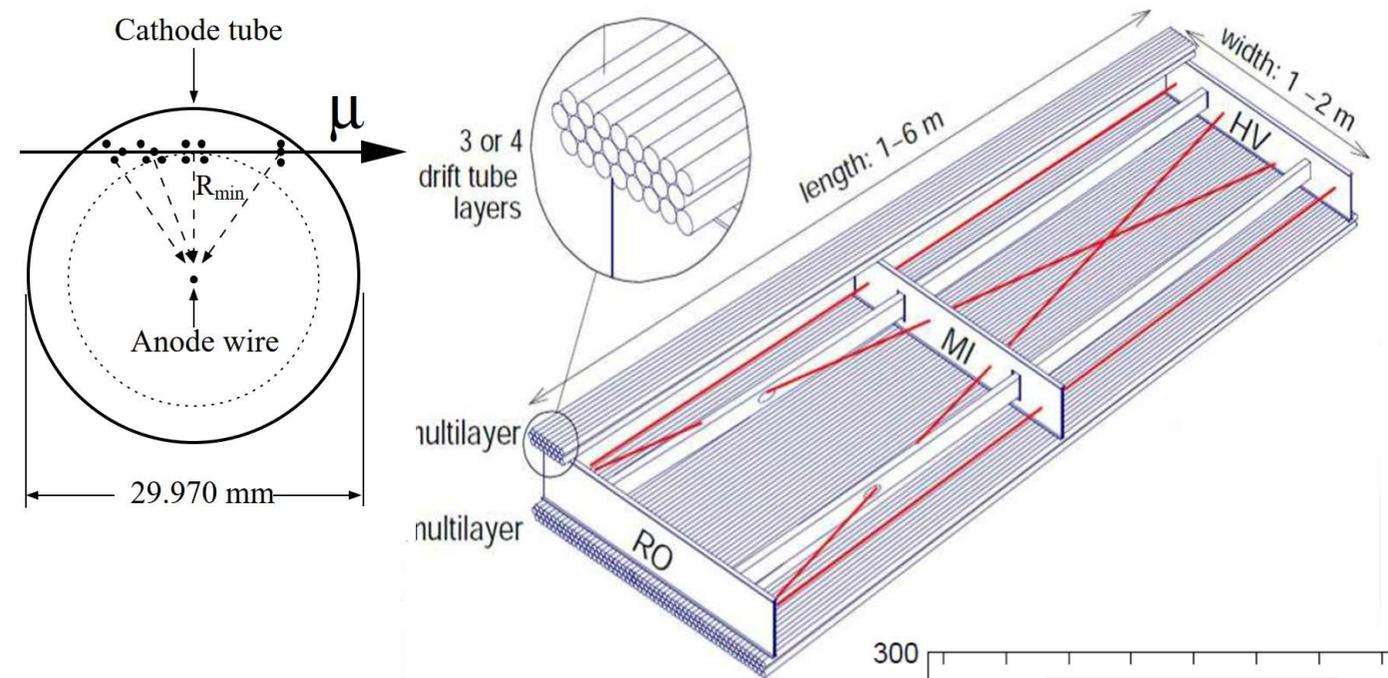

49 Time development of an avalanche in a proportional counter<sup>30</sup>). A single primary electron proceeds towards the anode, in regions of increasingly high fields, experiencing ionizing collisions; due to the lateral diffusion, a drop-like avalanche, surrounding the wire, develops. Electrons are collected in a very short time (1 nsec or so) and a cloud of positive ions is left, slowly migrating towards the cathode.

# ATLAS Muon Drift tubes

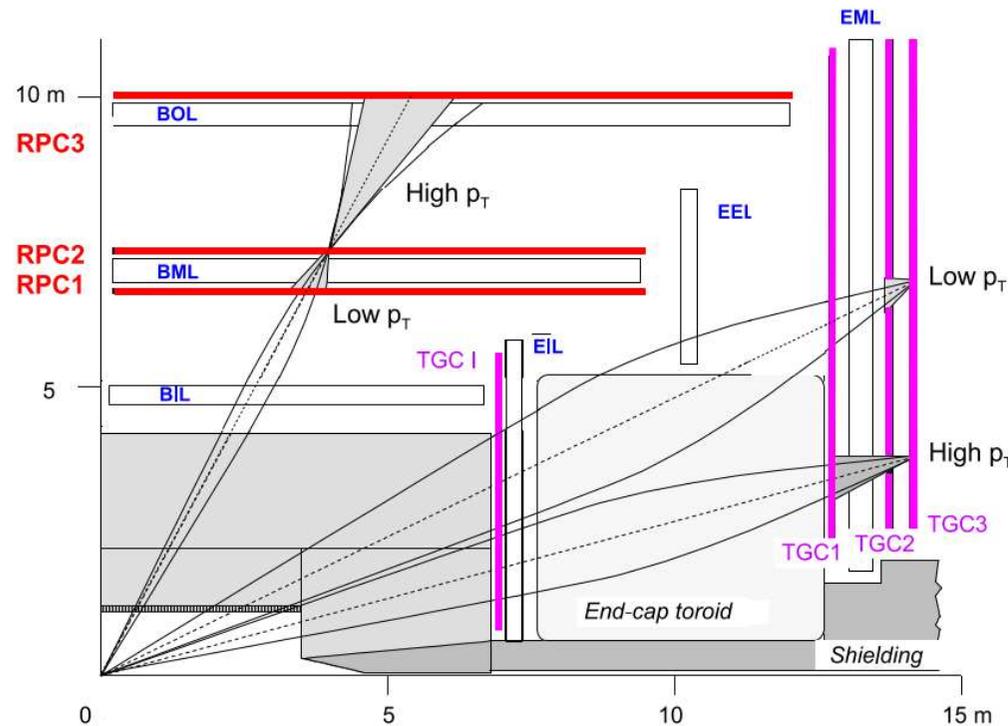

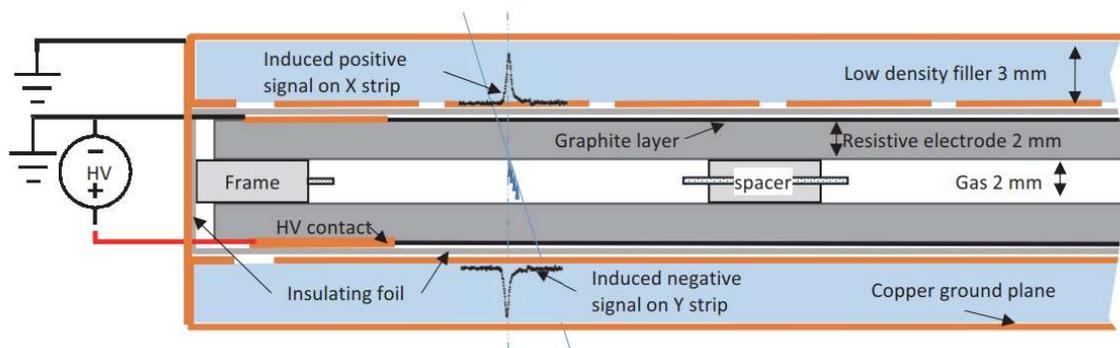

- 30 mm diameter
- 50 μm wire diameter
- Ar/CO<sub>2</sub>+H<sub>2</sub>O gas mixture
- 20000 gain at 3080 V
- 700 ns max drift time
- Point resolution ~100 μm

$$\sigma_r = v_d(E(r))\sigma_t \oplus \sqrt{2Dt}$$

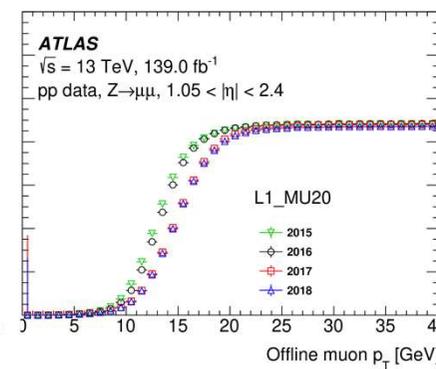

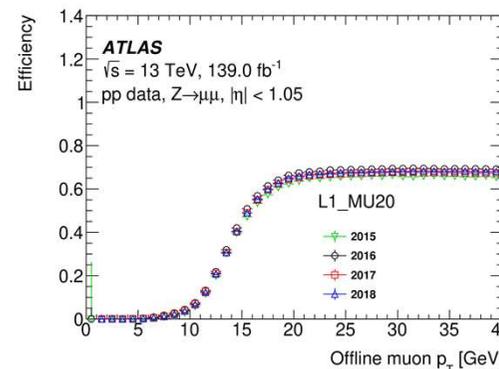

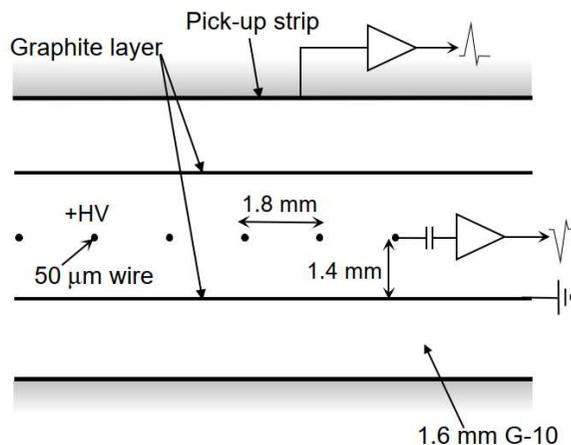

## RPC

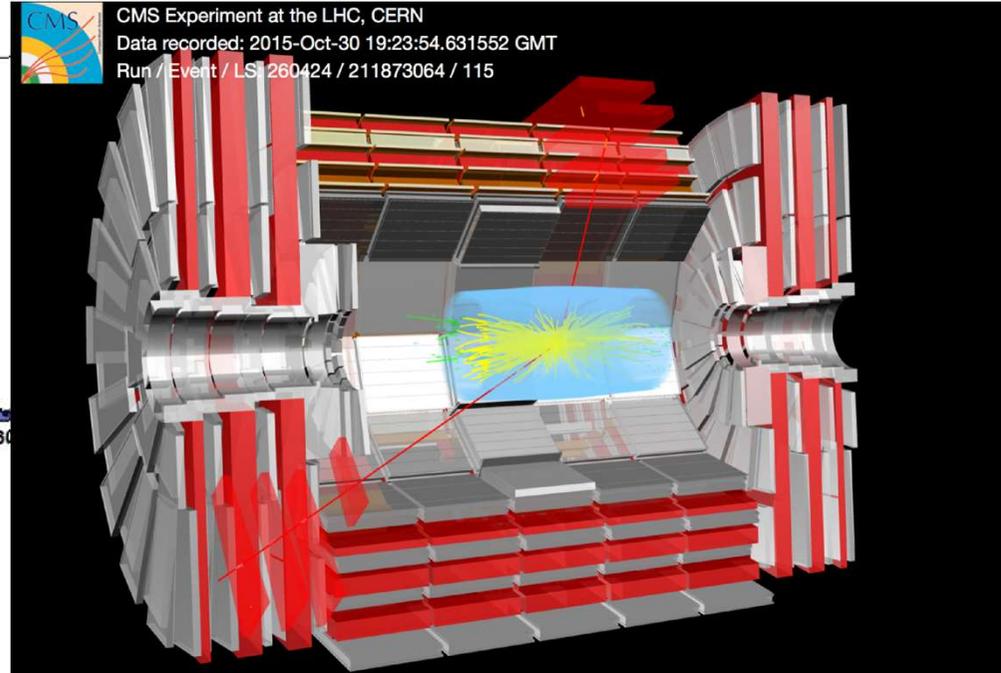

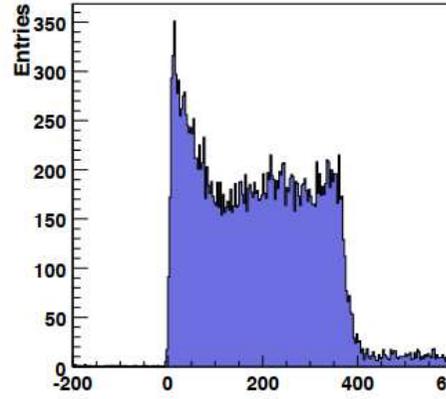

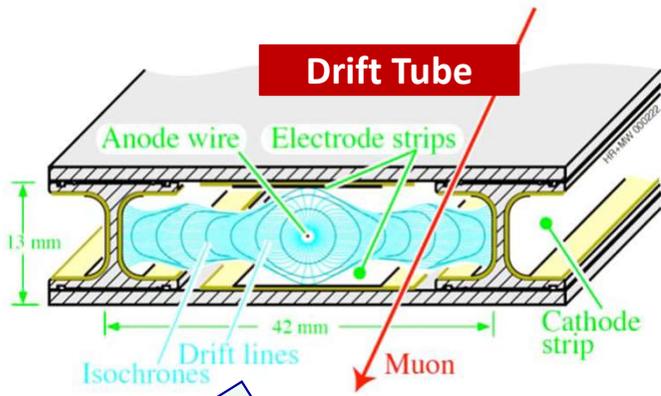

- Parallel plate capacitors with high electric field
- $E = 4.8 \text{ kV/mm}$ , gain  $10^7$
- Time resolution 1.9 ns

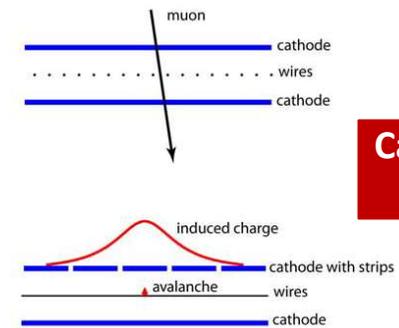

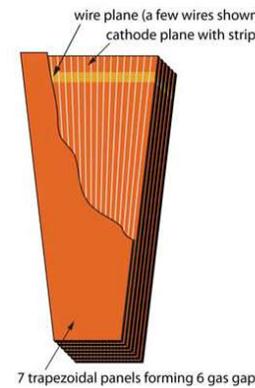

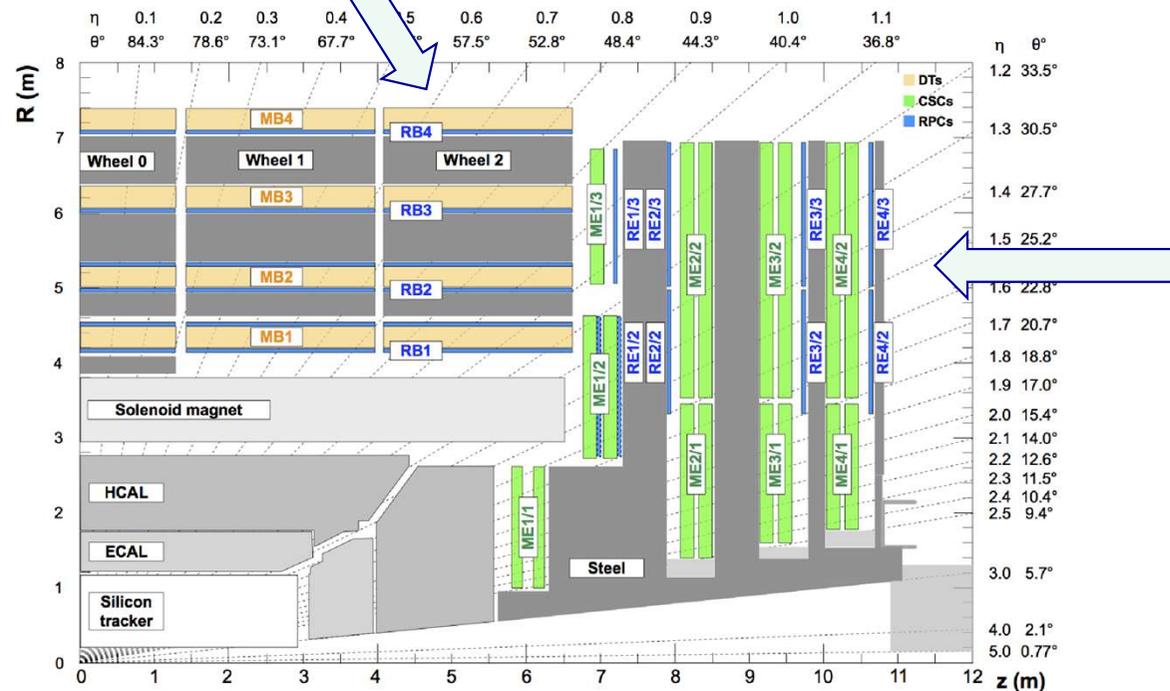

## TGC

- Proportional chamber with small gas gaps
- $50 \mu\text{m}$  anode wire
- Gain  $3 \times 10^5$  at 2.9 kV
- Response time  $< 25 \text{ ns}$  with 99% probability

CMS Experiment at the LHC, CERN  
Data recorded: 2015-Oct-30 19:23:54.631552 GMT  
Run / Event / L1 / 260424 / 211873064 / 115

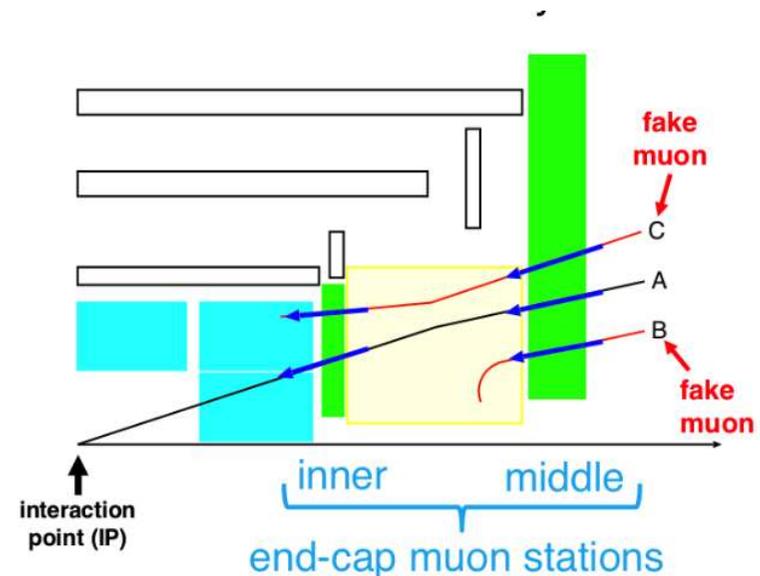

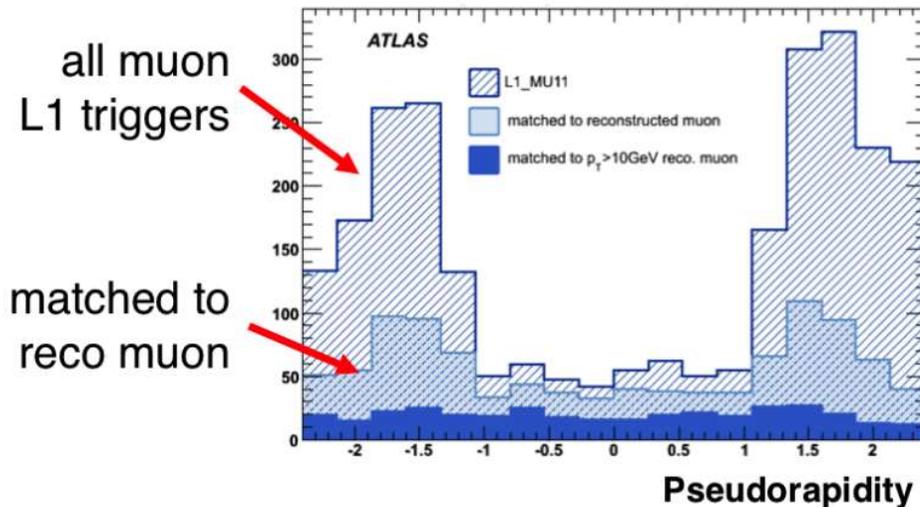

**Cathode Strip Chamber**

- Drift Tubes (barrel) and Cathode Strip Chambers (endcap) for trigger+tracking
- RPC for trigger with 1 ns time resolution

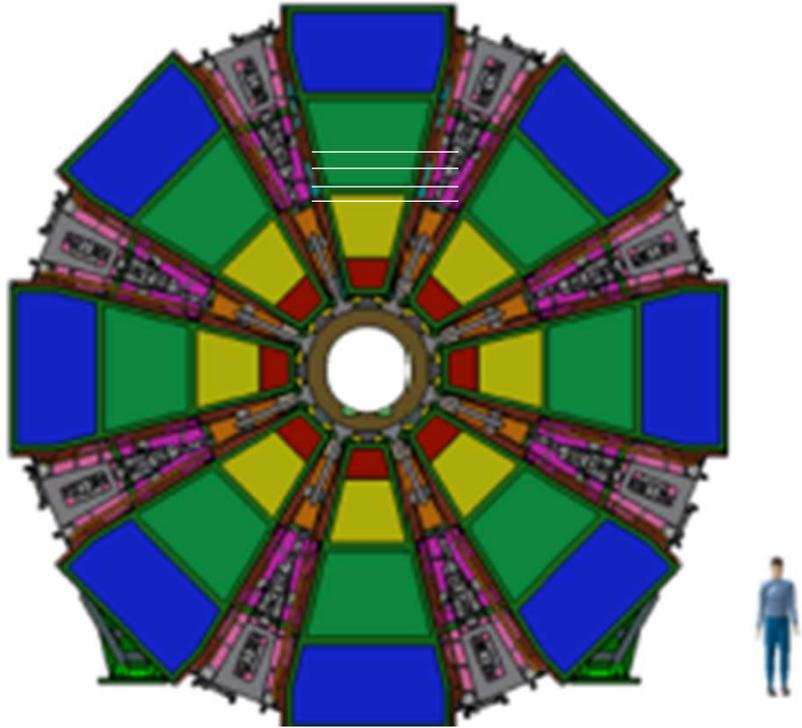

- Detector for the muon systems where initially designed for:
  - the nominal LHC rate corresponding to  $10^{34} \text{ cm}^{-2}\text{s}^{-1}$
  - radiation damage corresponding to a total integrated luminosity of  $500 \text{ fb}^{-1}$
- Many different interventions are needed to cope with the higher particle rate (in particular electronics improvement)
- Radiation damage  $\sim$  released charge per unit area/length
  - can be tuned by reducing gain at the cost of performance
- I'll shortly discuss only two upgrades:
  - addressing the most critical **forward region** deploying large areas for **micropattern gas detectors**

- Most L1 muon trigger in the forward regions are fake.
  - They need to be rejected more efficiently to stay within the HL-LHC trigger rate budget
- Match between track segments before and after the forward toroid
- The current detector has not the efficiency and accuracy needed
- **Replace the detectors in front of the toroid with New Small Wheels (NSW)**

- Detector requirements:
  - contribute to L1 trigger
  - reconstruct online track segments with >95% efficiency
  - position resolution <50  $\mu\text{m}$
  - angular resolution <1 mrad
  - sustain rate and radiation levels at HL-LHC
- Replace CSC+MDT with **Micromegas** detectors for precision tracking
- Replace TCGs for **sTGC** for trigger

# ATLAS New Small Wheels

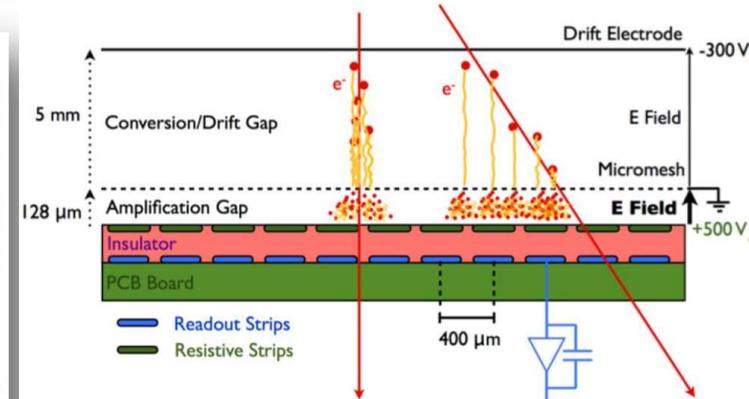

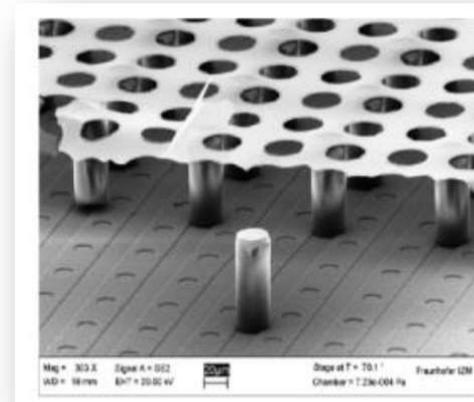

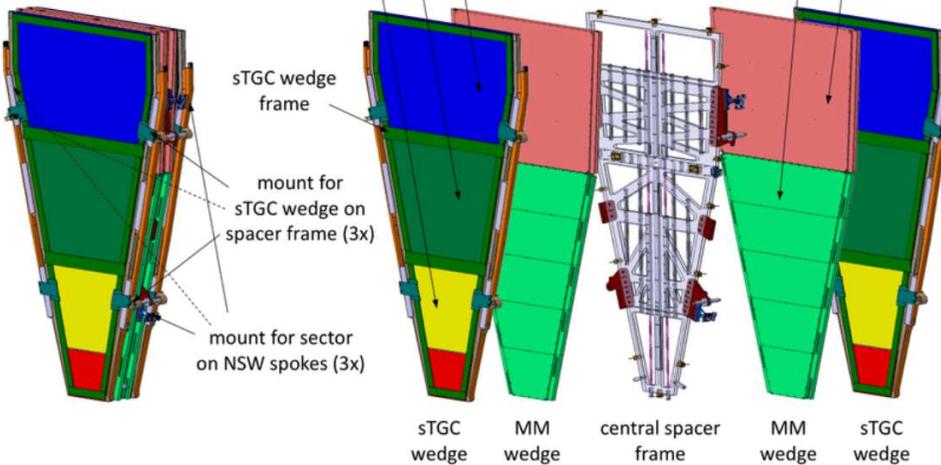

- Micromegas detector
  - micromesh transparent to electrons
  - separate the drift and charge multiplication region
  - finely segmented readout pitch
- NSW parameters
  - Ar/CO<sub>2</sub> 93%/7%
  - Short drift time: 100 ns
  - Spatial resolution <50  $\mu\text{m}$

NSW large sector (assembled view)

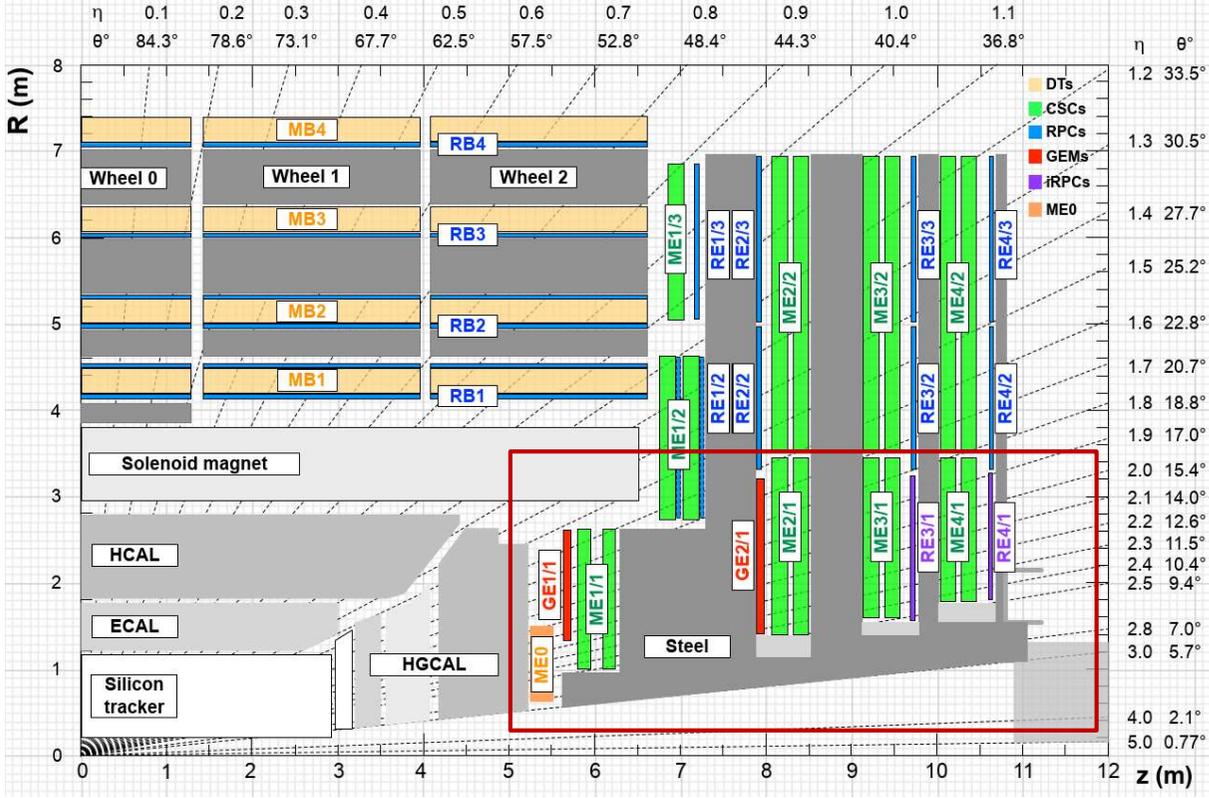

sTGC modules L1 - L2 - L3

NSW large sector (exploded view)

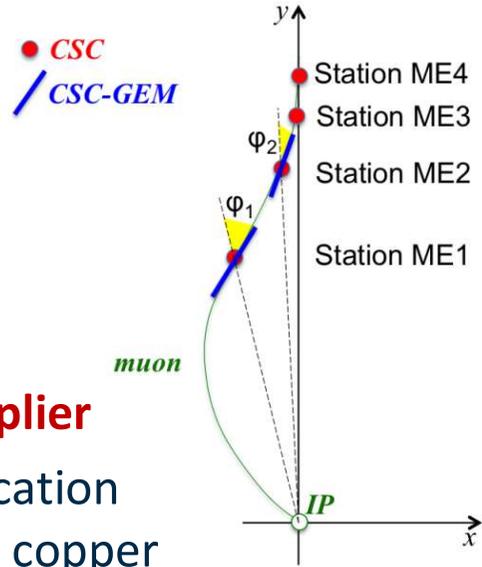

Micromegas modules LM1 - LM2

# CMS Forward region upgrade

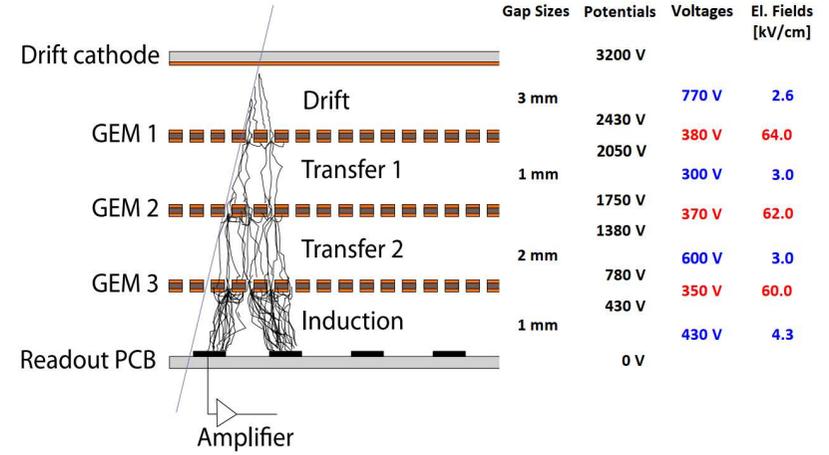

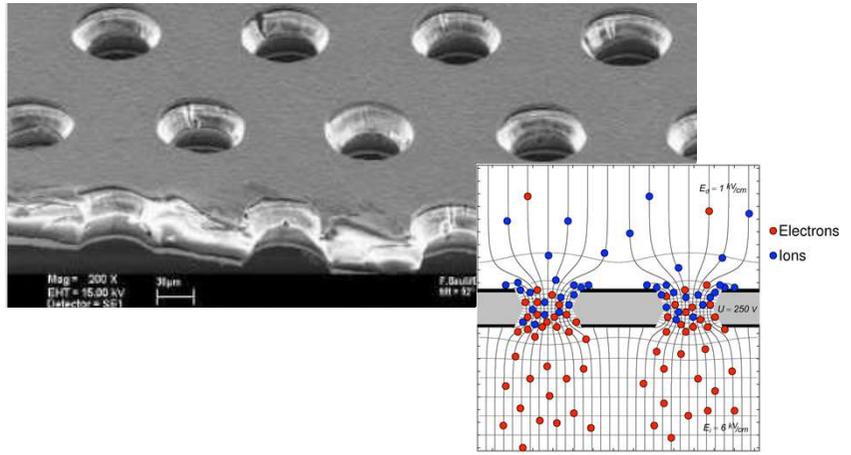

To cope with the high rate of particles in the high- $\eta$  region, redundancy need to be added.

## Gas Electron Multiplier

- charge multiplication inside gaps of a copper coated kapton foil
- most ions collected in the foil
- stacked to improve performance

# CONCLUSIONS

Istituto Nazionale di Fisica Nucleare

**Sezione di Milano**

**UNIVERSITÀ DEGLI STUDI DI MILANO**  
DIPARTIMENTO DI FISICA

- LHC has exceeded the design expectation
  - the machine is already running at twice its design luminosity
  - detectors are behaving greatly, despite the harsher conditions
  - ...and you will see physics analysis are doing even better
  - I hope to have shown you the key techniques and choice that made that possible
- The HL-LHC upgrade is not a free lunch
  - an enormous amount of time and ingenuity has been spent to prepare the detector upgrades
  - that sometimes required to find innovative solutions to old problems
  - hope to meet you again in seven years and celebrate success
  - for the time being....

**Thanks for giving me the opportunity  
to share my enthusiasm with you**
