TASS
Trigger and Acquisition System Simulator
An interactive graphical tool for DAQ and trigger design
Vers. 4.4

TASS
Trigger and Acquisition System Simulator

An interactive graphical tool for Daq and trigger design

Visit www.top1.it
TASS is a simulation program with graphical and interactive interface. It reproduces in a realistic way the commercial Nim, Camac and Vme modules. Both the front panel appearance and the electrical and logical behaviour are simulated. As in real world, the user can:

- push buttons and move switches
- turn knobs
- set Camac/Vme registers
- ... and so on
Example of a small setup (partial view)

Magnification of part, real view on pc screen
Project goal

TASS is devoted:

• To help experimental physicists developing their trigger systems.

• To help the students learning the fundamental aspects of this job.

Indeed ....
... up to now, the design and construction of a trigger system has been based on the experience of its designers and the simulations always based on software programs.

On the other hand, the transfer of know how among the members responsible of trigger systems can become very difficult if based only on pencil and paper and thousands of lines program code.

Therefore an interactive graphical tool becomes an essential part of the trigger design process.
How TASS Works

TASS program has been developed having in mind what the user does in the real world.

Indeed...

TASS provides a picture of a virtual electronic counting room. There, user can allocate racks, crates, fan units ... and so on, as in real setup.

TASS provides tools usually found in an experimental area like digital scope, wave generator, voltmeter, etc.

The user builds his own simulated trigger system choosing from a library the modules he needs, places them in the crates, makes the cable connections and runs the simulation.
Any parameter can be set interactively and input signals, provided either by a waveform generator or by a data file, can be used to stimulate the system. The resulting output can be shown on a virtual digital scope and saved on data files.

The simulation is “event driven”, an event being a change in the level of a signal.

Each time an event occurs, the program computes the transfer function of all modules whose inputs are affected by that event and reflects the changes on their outputs.
The advantage of this philosophy is that the user can change and try, very quickly, different configurations for the system under construction, by simply replacing modules and cable connections.

Since the complete hardware behavior is simulated, these actions will reproduce effects exactly corresponding to those of the real system.
Main features

The simulation can run continually or step by step.

Time is internally stored by 64 bits (19 digit) allowing a total simulation time longer than 10 days with resolution better than ps.

User can set breakpoints to halt the simulation if a predefined event occurs.

There are three type of breakpoint:

- BrkP break and pause simulation
- BrkW break and write to file
- BrkI break and send interrupt to the Daq program
Using programmable devices (Camac and Vme) the user has to provide an external Daq program steering the flow of command to the hardware.

A library of Esone routines and general Vme support functions is provided.

TASS supports hardware interaction by

- Look At Me (LAM) interrupt
- Polling techniques

A histogramming library, similar to HBook, is available.
Main features - cont

TASS adopts a powerful cabling technique:

- Nim, Ecl and 3M bundle flat connection allowed.
- Cable’s length (in ns, scaled to real world) is automatically computed.
- Automatic check of plug and cable consistency.
- Capability to label any cables.
- Complete list of properties of any connections.
- Statistic for cable length.

TASS supplies automatically:

- The picture of layout of the trigger system (counting room)
- The picture of any crate
- List of used crates
- List of used modules
- List of used cables
- List of connections
Integration with the real Daq program

Full integration with the real Daq program can be easily achieved by the exchange of Camac / Vme commands via Tcp/Ip communication.

TASS provides suitable RemoteDaq class to interface Daq programs written in C++, Java, Visual Basic, and LabView languages. The supplied RemoteDaq class allows writing the Daq Camac/Vme calls in the same way as in the real world making the translation process, between the external Daq environment and the TASS system, fully transparent from user’s point of view.

This feature allows to the user to develop and test her/his Daq program also in absence of real hardware.
Full integration with the real Daq program

**RemoteDaq class** provided for:
- Visual Basic
- Java
- C++
- Lab View

```java
//define Camac register Adc0
Camac.CDREG (Adc0, br, cr, Adc0Stat, SubAdd0);

//define Camac register StatA
Camac.CDREG (StatA, br, cr, StatAStat, SubAdd);

//initialize Camac crate
Camac.CCCZ (Adc0);

//Write StatusA Mask
Camac.CSSA (17, StatA, Mask, q);

//Enable ADC Lam
Camac.CSSA (26, Adc0, Data0, q);
```
Possible application

- **Design, optimization and documentation of the trigger system in physics experiments.**
  
  This is the main TASS goal. Several different configurations can be tested without the need to have the real modules available. Also the importance of being able to reproduce the system behavior corresponding to an ‘old’ configuration should not be underestimated.

- **Development and test of DAQ program.**
  
  During the development of DAQ program, the real trigger can be replaced by its TASS simulation. No real hardware need to be involved.

- **Monitor and on line debugging of real systems.**
  
  Making the comparison between the real output and the simulated one, a hardware fault can be prompt discovered (see manual).
Possible application

- **Evaluation of hardware dead time and efficiency.**
  TASS keeps trace of delays and duration time of signals of any module, cable connections and so on. Evaluation of hardware dead time and efficiency are built-in in TASS output.

- **Speed up of the tuning phase in beam activity.**
  Most of beam time spent to tune the real system can be saved if any critical part has been simulated in advance. This can be extremely important in case of short beam allocation periods (test beam experiments).

- **Student and on line team training.**
  TASS offers to students and instructors the ability to quickly design and test general-purpose systems without any real available modules. Training of online team for trigger system diagnostics should also be considered.

- **Framework environment changes.**
  Changes to the real trigger can be simulated in advance avoiding to modify or dismount the existing set up.
Conclusion

- So far more than 50 modules are simulated.
- Full package consists of more than 500k code lines.
- The package includes a “Device Editor” that allows user to develop code for modules not present in the library.

We think that TASS may represent a novel approach to the problem of simulation of complex trigger systems in HEP. Its modular structure allows a simple procedure to test different trigger setup. Its interactive behavior will be of great help in understanding problems that sometimes appear only after off line data analysis.

A demo package comprehensive of many examples is free available on WEB at:
