### Introduction

- Future hadron colliders challenge the tracking and reconstruction with high rates and huge pile-up
- ATLAS and CMS already aim for 30-40ps timing resolution, future trackers like FCC will demand timing of 5ps while still providing position resolution below 10 μm in high density environments
- High radiation doses challenge the sensors additionally
- Silicon sensors are proven to be very radiation hard and have a short charge collection time – current and future choice for tracking detectors
- Many collaborations working on improving time resolution, e.g.
  - Ultra Fast Silicon Detectors (UFSDs LGADs)
  - 3D pixel sensors dedicated for timing

Tracking z-resolution larger than vertexseparation: Ambiguous Track-to-vertex association

### LGADs and 3D sensors

Low Gain Avalanche Diodes (LGADs)

**3D Sensors** 

- Avalanche region creates fast and high signals
- LGADs with different gain layer doping tested
- $50 \ \mu m$  active thickness
- $1.3 \times 1.3 \ mm^2$  area
- Produced by Hamamatsu (HPK Run 2)

- Junction columns etched into the sensor bulk
- Strip and pixel sensors tested
- 235  $\mu m$  active thickness
- Strips:  $80 \times 80 \mu m^2$  cell size
- Pixels:50  $\times$  50  $\mu m^2$  cell size
- Produced by CNM

## Experimental Setups

- Single pulses recorded of both reference and tested sensor
- About 3000 events with DUT signature for appropriate statistics
- If possible, only external triggers

- <sup>90</sup>Sr-source
- LGAD reference,  $\sigma_{Ref} = 25.18 \pm 0.35 \ ps$
- PMT yes/no trigger

- Top-TCT, infrared laser (1060nm)
- 2 pulses recorded (fiber splitter)
- Intensity tunable

Leena Diehl - Comparison of the time resolution of unirradiated and irradiated LGADs and 3D sensors

### Time Resolution: LGADs -Beta

- From high (Split 1) to low (Split 4) gain layer doping increase in voltage necessary
- Lower doping reaches in total better resolution at highest voltages
- Irradiated sensors still working, reaching approximately the same resolution as an unirradiated sensor

2/07/2022

### Time Resolution: LGADs - TCT

- No Landau fluctuation in TCT setup significantly smaller time walk contribution
- No gain layer suppression (broad laser beam): Steeper improvement of the time resolution (stronger increase in signal)

### Time Resolution: 3D Pixel Sensors

- Before irradiation, sensors reach about 30-31 ps time resolution at room temperature
- After irradiation the sensors reach 26.7 ps (1e15) and 24.5 ps (5e15) at -18.5°C
- Signal decrease for sensor at 1e15, but increase at 5e15 hints to charge multiplication

Leena Diehl - Comparison of the time resolution of unirradiated

and irradiated LGADs and 3D sensors

### Time Resolution: 3D Pixel Sensors

- Rise time significantly lower for 5e15, similar to unirradiated for 1e15
- Jitter for irradiated sensors slightly lower (measured cold)
- Smaller voltage dependence for rise time and jitter of the irradiated sensors
- Lower noise for 1e15 (cold measurement), but significantly higher for 5e15 hint for charge multiplication

Leena Diehl - Comparison of the time resolution of unirradiated

and irradiated LGADs and 3D sensors

### Comparison – LGAD vs 3D Pixel

- No large voltage increase after irradiation for the 3D sensors
- Significantly lower rise time
- For this 3D pixel and LGAD types: 3D sensors perform better in timing measurements
- Note: This are not the latest/ fastest generation of LGADs but the 3D sensors prove to be competitive

### Time Resolution: Unirradiated 3D Pixel Sensors

- Time resolution measured at 60 V for a 10x40  $\mu$ m area in 5  $\mu$ m steps and interpolated
- Both sensors: Similar cell structure recognizable :
  - Better resolution closer to the readout column
  - Worse resolution closer to the other junction columns
  - Range from 23-43 ps/ 25-47 ps
- Differences: Uncertainties in position, laser focus, laser intensity

10 **N** 

### Time Resolution: Unirradiated 3D Pixel Sensors

- Low laser intensity MPV around 80-110 mV, low compared to beta set-up (145 mV)
- Cell structure not as clear as for time resolution, but still fits the expectations
- Rise time between 340 and 420 ps, higher than measured in the beta set-up

Leena Diehl - Comparison of the time resolution of unirradiated

and irradiated LGADs and 3D sensors

11

IBURG

- 3D strip sensor: 235  $\mu$ m thickness, 80x80 $\mu$ m<sup>2</sup> cell size, 6 channels connected to readout
- Measured with TCT and Timing Set-Up
- For high voltages: Time resolution of about 75 ps reached

ZW

Position dependent measurement of the time resolution with the TCT, measured at 150 V

Leena Diehl - Comparison of the time resolution of unirradiated and irradiated LGADs and 3D sensors

- Clear cell structure
  - Similar patterns for jitter and rise time
- Both correlate to the expected el. Field
- Rise Time between 810 and 855 ps
- Jitter higher than in Beta Set-Up, 52-62 ps

14 LA

### Conclusion and Outlook

- Time resolution of silicon sensors is an important research area for upcoming and future colliders
- Before irradiation, both LGADs and 3D sensors reach a comparable time resolution of 30-35 ps
- After irradiation, the LGADs need significantly higher bias to maintain a similar resolution
- 3D pixel sensors improve resolution after irradiation while the bias voltage range stays the same
- At a fluence of  $5 \times 10^{15} n_{eq}/cm^2$  the 3D pixel sensors show signs of charge multiplication
- The position dependent time resolution measured correlates very well with the electric field distribution
- **Outlook**: Test of higher irradiation doses and different 3D sensor geometries, including sensors designed specifically for timing purposes (dedicated 3D timing project)

### LGAD Readout Board

- 1. Bonded LGAD
- 2. Amplifier
- 3. High voltage connector
- 4. Readout connector
- 5. Low voltage connector
- 6. PT100 connector
- 7. Lid

### Time Resolution - Components

Main components: Jitter and time walk:

• Jitter component  $\sigma_j$ : Determined by the rise time at the amplifier output dV/dt and the noise level  $\sigma_n$ :

$$\sigma_j = \frac{\sigma_n}{|dV/dt|} \approx \frac{\sigma_n}{|S/\tau_p|} = \frac{\tau_p}{S/N}$$

 $\sigma_t^2 = \sigma_i^2 + \sigma_{TW}^2$ 

- Time walk component includes:
  - Weighting field/ el. Field contribution
  - Landau fluctuations in signal shape
  - Landau fluctuation in the amount of deposited charge (correctable)
- Time Walk component depends strongly on the sensor design

## TCT Set-Up for Timing

- Transient Current Technique: Charge created by a short laser pulse
- The current arising from the created e/h-pairs is amplified and then recorded with an oscilloscope
- Top-TCT: Laser on sensor surface, laser wavelength 1060 nm (infrared)
- First: Scanning the sensor area to determine the position of the columns
- For each specific position on the sensor: 3000 single events recorded
- Two pulses recorded per event: Using a fiber splitter and a cable (25 ns delay)

# TCT Set-Up for Timing

- Intensity regulation: Neutral Density Filter transmitting only 25% of light
- TCT-Timing measurements have several difficulties:
  - > Finding the focus on tiny devices such as the 3D pixels is tedious
  - > Without focus, problematic to find the metal opening at all
  - During the timing measurements: Position insecurities, as the laser has to be moved by hand with another software for each step (automated software still in development)
  - Gaussian laser beam and reflections back into the sensor from backside decrease position resolution further
- Freiburg is one of very few institutes able to successfully perform TCT-Timing measurements so far the only one testing 3D-sensors with it

# Beta Set-Up for Timing

- LGAD as reference sensor
- Scintillator & PMT as Yes/No trigger
- Reference and DUT signal recorded for each event

- Trigger on LGAD and PMT: 10000 events recorded, about 1/3 show a DUT signature
- Trigger on LGAD and DUT: 3000 events recorded, necessary for thicker devices or extremely small sensors

UNI FREIBURG

### Time Resolution: Analysis

- Maximum amplitude for each event filled into histogram MPV of the sensor is extracted with a Landau-Gauss-Fit
- If the maximum signal is above a threshold, events used for further analysis
- Time of Arrival determined with Constant Fraction Discrimination
- Linear fit around this point to extract the slope
- Determination of the rise time for each event by diving the maximum amplitude by the slope – mean of the distribution defines rise time

### Time Resolution: Analysis

- Noise level: Determined in a time span in the recorded waveform before the pulse
- Jitter: Sigma of a Gauss fit to the distribution of noise divided by slope
- Time Spread: Sigma of a Gauss fit to the distribution of the time difference between the two signals
- Time resolution can then be calculated

 $\sigma_{Ref} = 25.18 \pm 0.35 \, ps$ 

Leena Diehl - Comparison of the time resolution of unirradiated and irradiated LGADs and 3D sensors

## Time Resolution: 3D Pixel sensors

- Sanity Check: Comparison with/without additional PMT trigger
- With PMT: Very low rate pick-up noise problems
- Without PMT: overestimation of MPV
- Otherwise: Very comparable results
- All further measurements without PMT improved statistics and measurement time, while time resolution characteristics are maintained

### Time Resolution: 3D Pixel Sensors

- TCT scans show very small measurable area for Timing-TCT
- Outer columns connected indefinite electric field outside the cell explains the higher time resolution
- For Timing-TCT: Measured with laser intensity similar to one MIP-equivalent
