

Look at the track hit efficiency and dE/dx of the BaBar drift chamber

Matteo Rama

Laboratori Nazionali di Frascati, INFN

thanks to Giulietto Felici, Giuseppe Finocchiaro, Marcello Piccolo

What has triggered the investigation

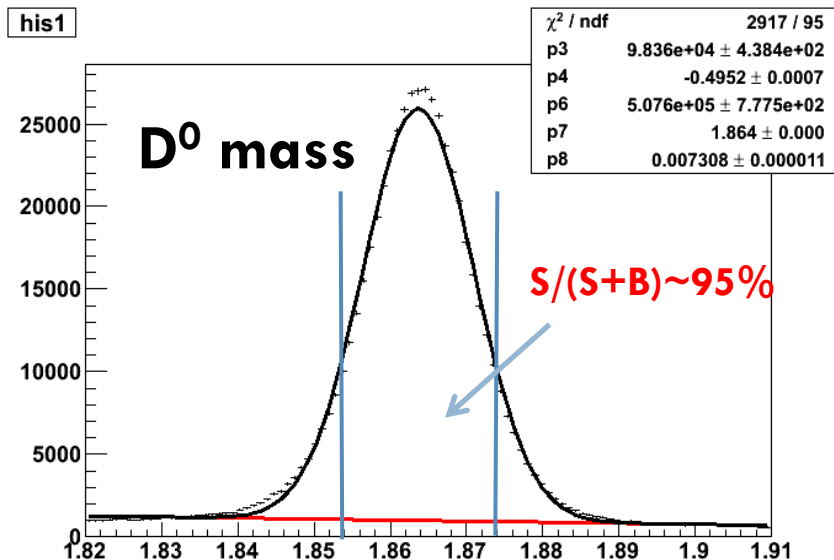

- In FastSim we want to implement reliable PID selectors built from the basic ingredients: dE/dx (DCH+SVT), DIRC, TOF, etc.
 - ▣ It requires a sufficiently precise description of each ingredient
- Use Babar data to study the performance of dE/dx and tune a realistic simulation of Babar and SuperB (the latter with possible modifications)
 - ▣ Observed some interesting features in the DCH hits distribution. Work still in progress.

Selection of pions, kaons and dimuons samples in Babar data

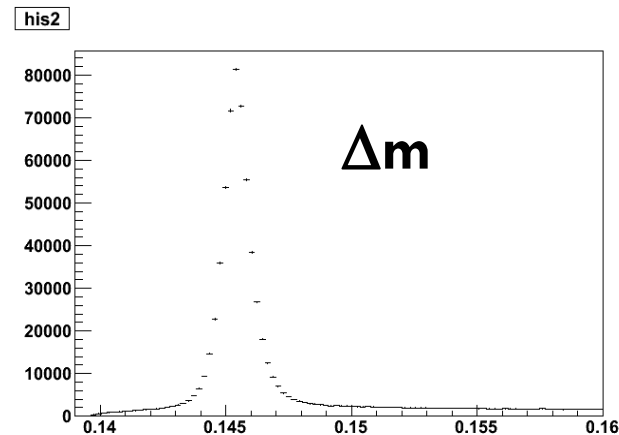

- Selection of $D^{*+} \rightarrow D^0 \pi^+$, $D^0 \rightarrow K^- \pi^+$ (+ c.c.)

$$|m_{D^0} - \langle m_{D^0} \rangle| < 1.5 \sigma$$

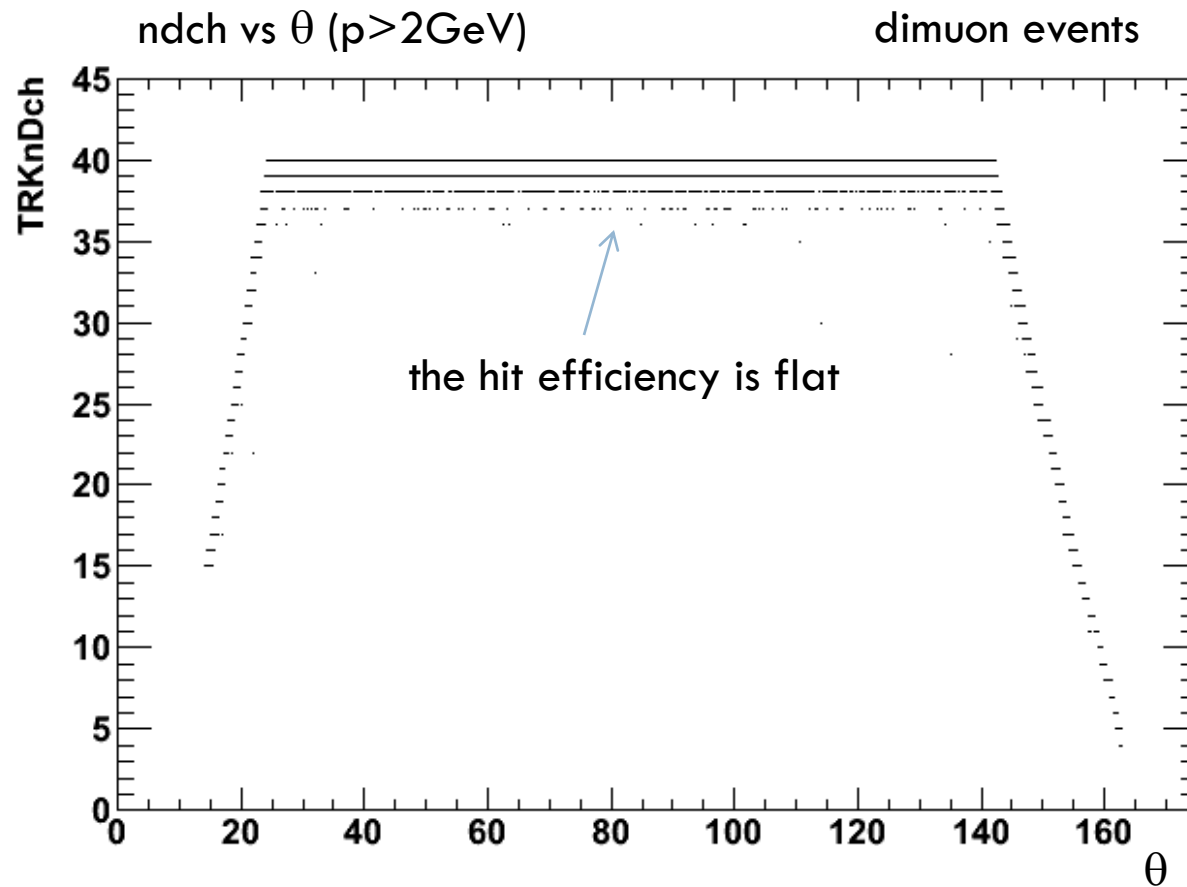

$$144.45 < \Delta m < 146.45 \text{ MeV}$$

- Selection of dimuons events
 - provided by the PID group
 - $n\text{Trk}/\text{evt} = 2$

DCH hits vs polar angle in FastSim

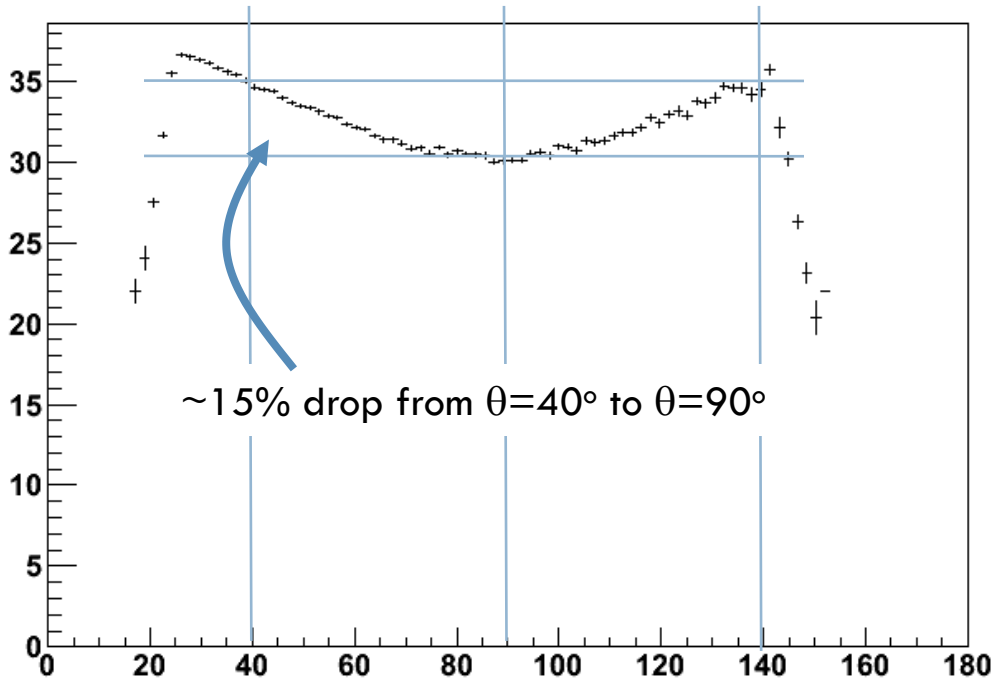

DCH hits vs polar angle in BaBar

(Run6)

pions from $D^{*+} \rightarrow D^0 \pi^+$, $D^0 \rightarrow K^- \pi^+$

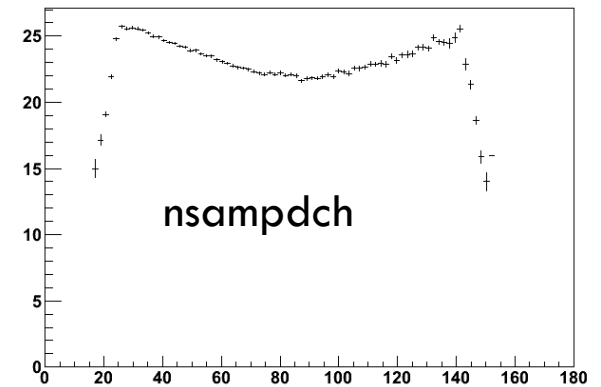

ndch vs θ (p in [1.9,2.1]) (pions with $p > 2$ GeV)

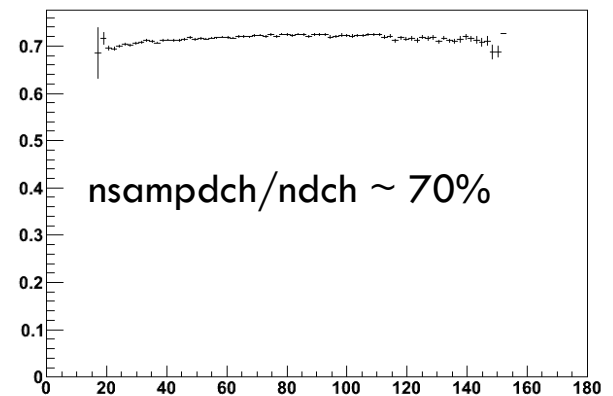

Is the pattern mainly caused by 'hit confusion' in pat. rec. due to the track multiplicity of the event? \rightarrow next slide

#hits used to evaluate dE/dx

nsampdch vs θ (p in [1.9,2.1])

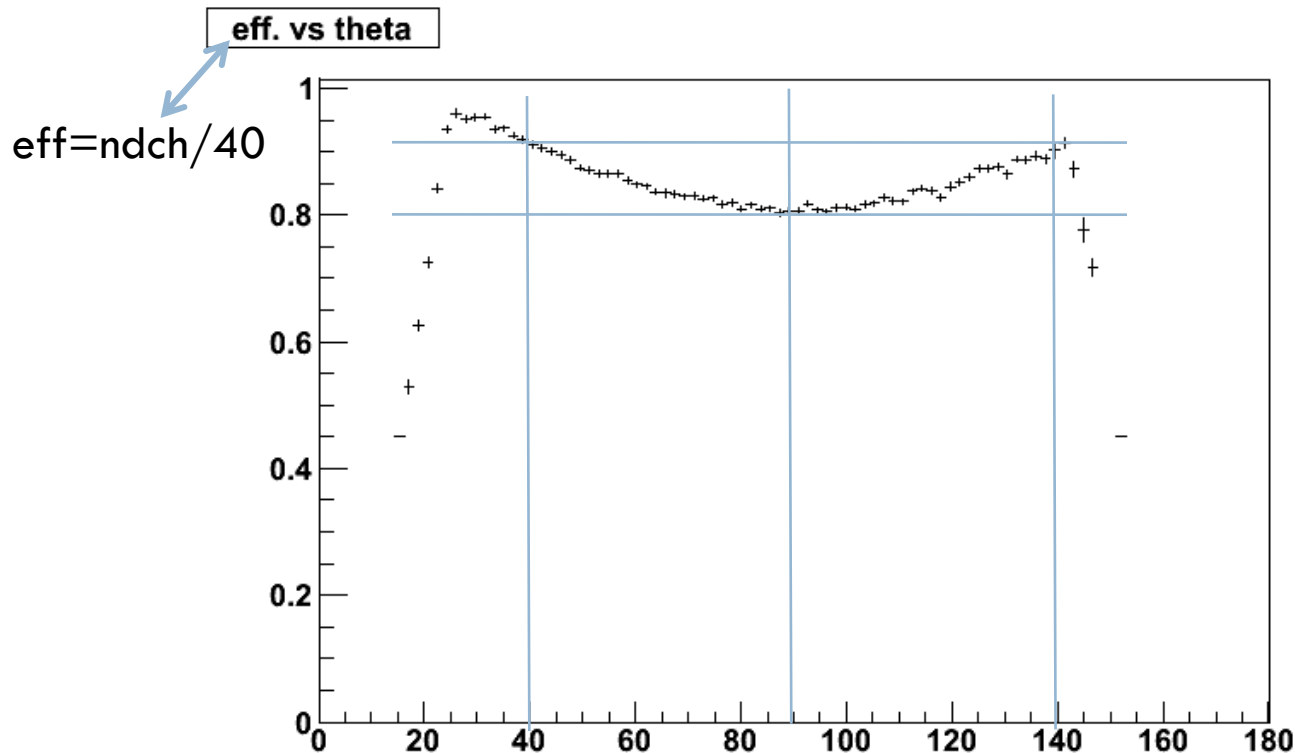

nsampdch/ndch vs θ (p in [1.9,2.1])

DCH hits vs polar angle in BaBar

dimuons events (nTracks/event = 2)

The pattern is still there even when the hit confusion is expected to be negligible

Note: the absolute efficiency is slightly increased (at $\theta=90^\circ$: 80% in dimuons, 75% in D*)

DCH hits vs polar angle in BaBar

dimuons events (nTracks/event = 2)

Consider a model where $dp = \lambda dx$

dp = prob. that the track generates a visible hit in a path length dx

$$\rightarrow \varepsilon = 1 - e^{-\lambda x}$$

expressing λ in terms of eff at $\theta=90^\circ$ (ε_1)
and adding a global eff on top of it (ε_0):

$$eff = \varepsilon_0 (1 - (1 - \varepsilon_1)^{x/h})$$

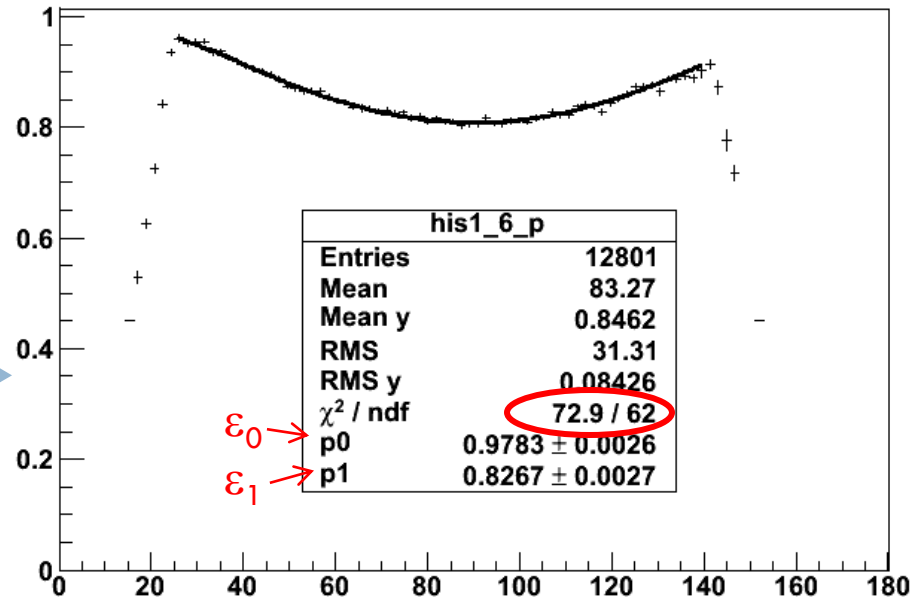

h = cell height (1.19cm)

this “threshold model” describes
the data very well

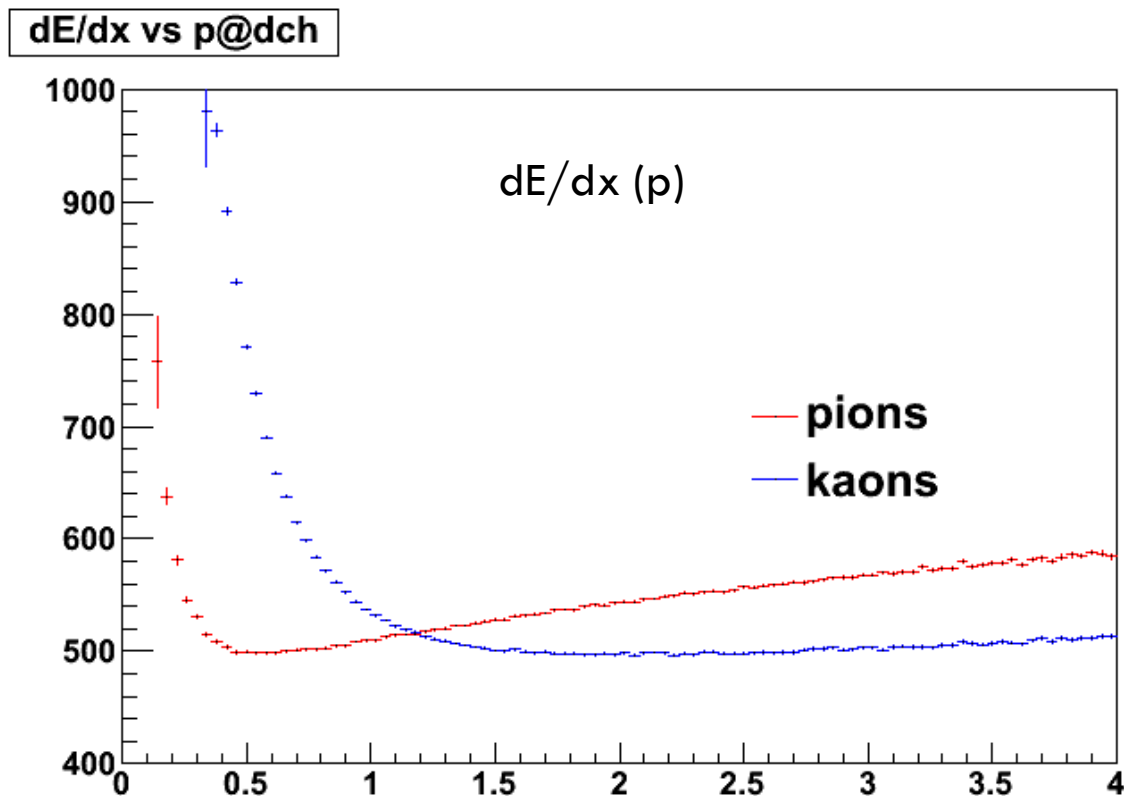

Can we check the correlation with
the amount of charge in the cell?

eff. vs theta $eff = ndch/40$

Correlation with the amount of ionization

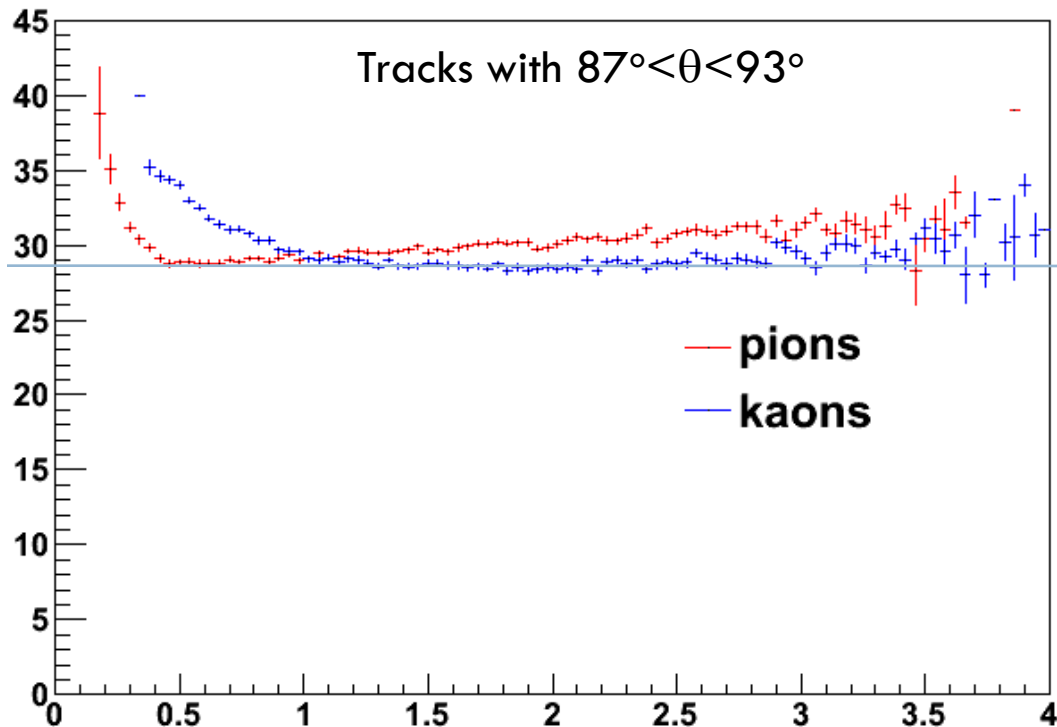

Use π and K from $D^{*+} \rightarrow D^0 \pi^+$, $D^0 \rightarrow K^- \pi^+$ to check if there is a correlation between the hit efficiency and the amount of ionization

Correlation with the amount of ionization

At $\theta=90^\circ$ there is a clear correlation between #hits and charge

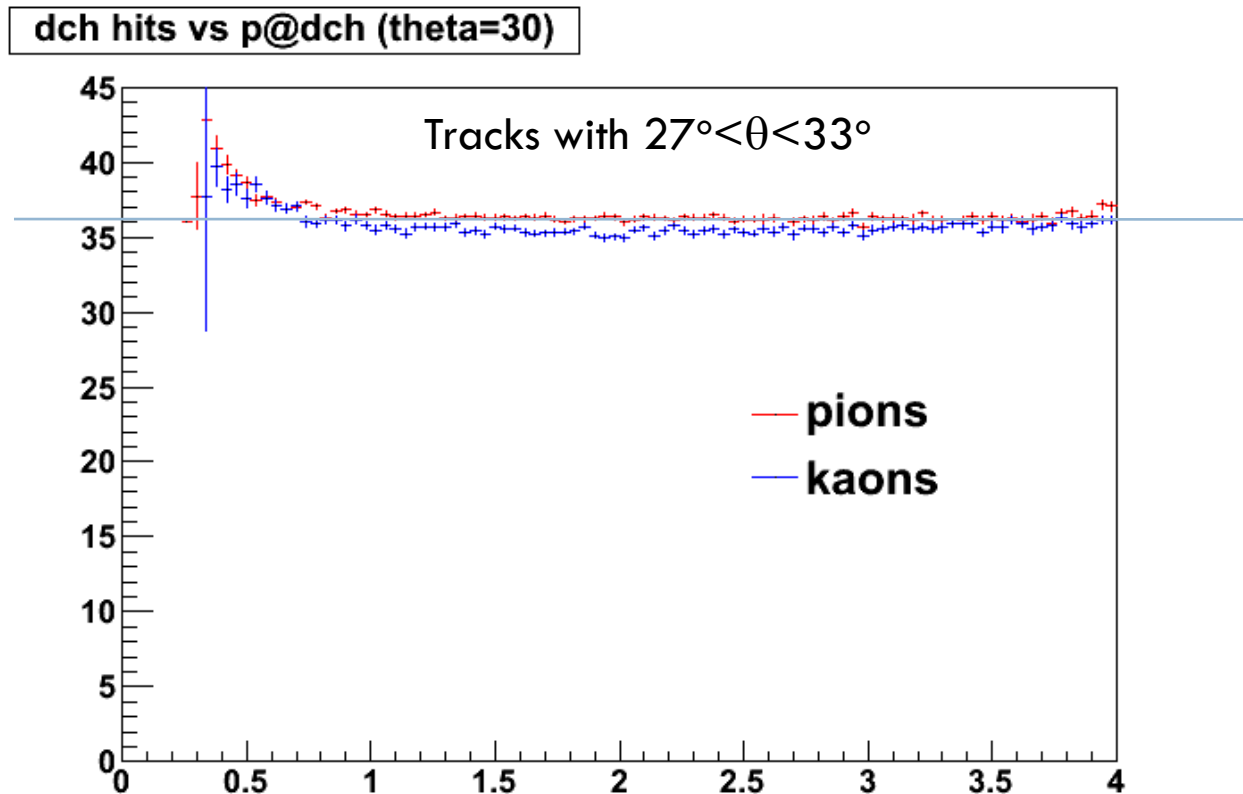

dch hits vs p@dch (theta=90)

Note: pions and kaons have the same path length in the cell

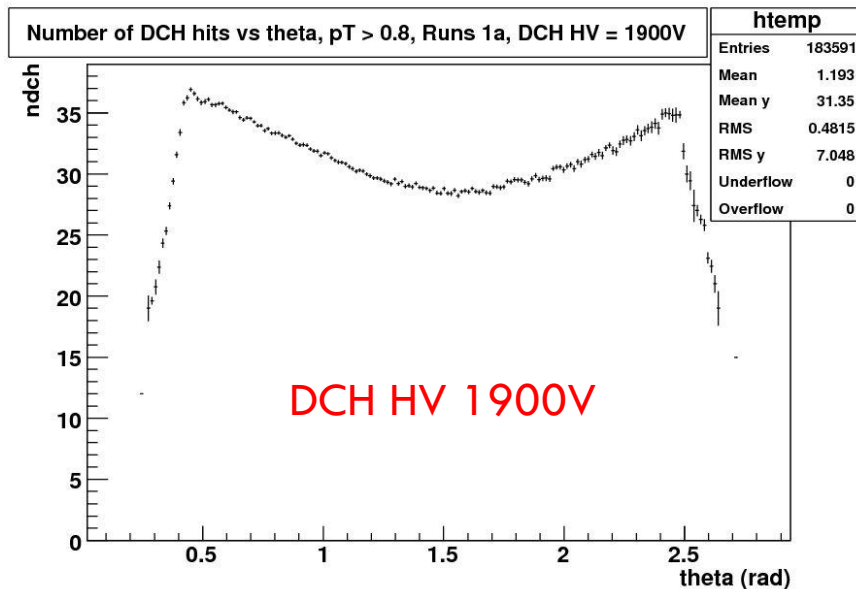

Correlation with the amount of ionization

At $\theta=30^\circ$ a saturation effect is visible

Correlation with the amount of ionization

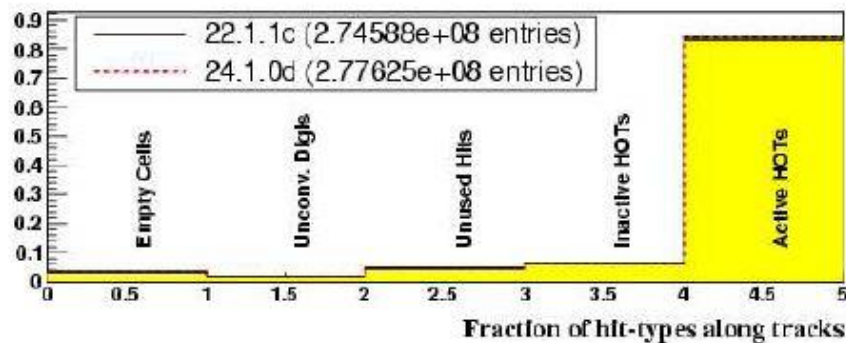

Another check: the efficiency increases with the DCH HV

plots by A.Telnov

Hit types along the track

Hit types along the track

From a slide of I. Ofte, BaBar CM Dec. 2007

The datasample and selection cuts are not specified

- Active HOTS: ~85%
- Inactive HOTS: ~6%
- Unused Hits: ~5%
- Unconv. digis: ~1%
- Empty cells: ~3-4%

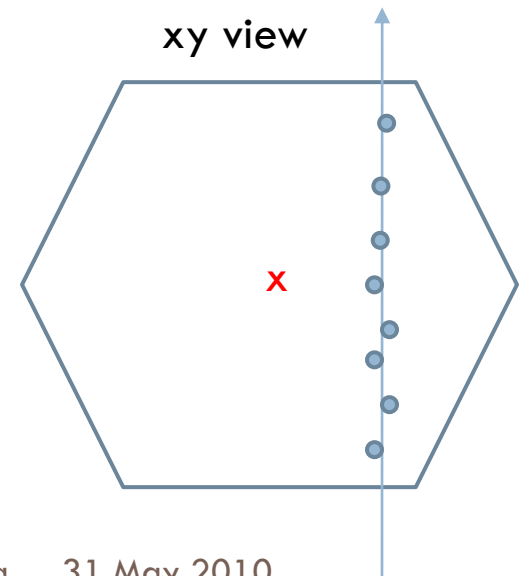

Hypothesis

hypothesis suggested by Giuseppe: effect related to the probability of losing the hits closest to the wire? (time displacement of cell hits)

from Babar NIM:

To reduce the time jitter in the signal arrival and at the same time maintain a good signal-to-noise ratio, the signal threshold was set at about 2.5 primary electrons.

Use of Babar data to tune the drift chamber dE/dx in FastSim

dE/dx simulation in FastSim

- $\langle dE/dx \rangle_{\text{hit}}$ is computed with the Bethe Bloch function and then smeared according to $\sigma(\langle dE/dx \rangle_{\text{hit}})$

- $\sigma(\langle dE/dx \rangle_{\text{hit}})$ is parameterized as

$$\sigma\left(\frac{dE}{dx}\right) = \alpha \left(\frac{dE}{dx}\right)^\beta dx^\gamma$$

where α, β, γ parameters are chosen as:

α = so that the K- π separation is consistent with plots in Babar BAD1500

$\beta = 1$

$\gamma = -0.5$

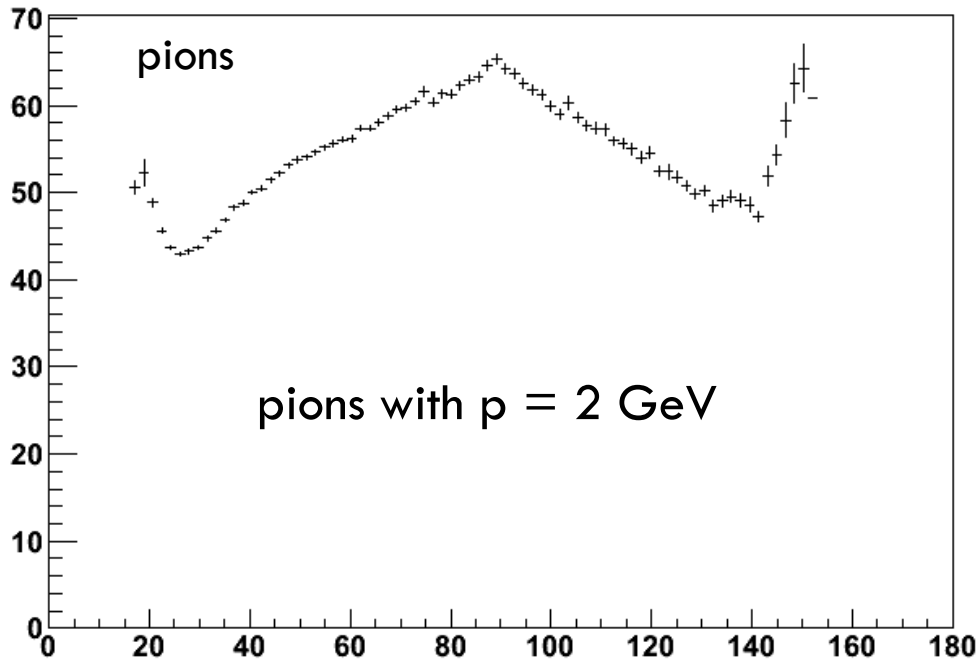

- $\langle dE/dx \rangle_{\text{track}}$ is measured as a 'random' truncated average of $\langle dE/dx \rangle_{\text{hits}}$

goal: determine α, β and γ from Babar data

$\sigma(dE/dx)$ vs θ (pions)

First, I use $\sigma(dE/dx)$ vs θ to measure γ :

dedxErr vs θ (p in [1.9,2.1])

$$\sigma\left(\frac{dE}{dx}\right) = \alpha\left(\frac{dE}{dx}\right)^\beta dx^\gamma$$

$$dx \sim h/\sin(\theta)$$

$h = \text{cell height}$

But before I rescale the distribution by $\sqrt{N_{\text{hit}}}$, **assuming that the error scales as $1/\sqrt{N_{\text{hit}}}$**

The result in the next slide

$\sigma(dE/dx) \text{ vs } \theta$ (pions)

$$f(\theta) = p_0(\sin \theta)^{p_1}$$

dedxErr*sqrt(nsampdch/40) vs θ (p in [1.9,2.1])		df	1181 / 70
p0			44.79 ± 0.04
p1			0.3321 ± 0.0024

$$p_1 = -\gamma$$

$\rightarrow \gamma = -0.33$
(it was set to -0.5)

Note 1: the normalization by $\sqrt{N_{\text{hit}}}$ has *almost* removed the peaks in the fwd/bwd regions

Note 2: the distribution is significantly fwd-bwd asymmetric

$\sigma(dE/dx) \text{ vs } \theta$ (kaons)

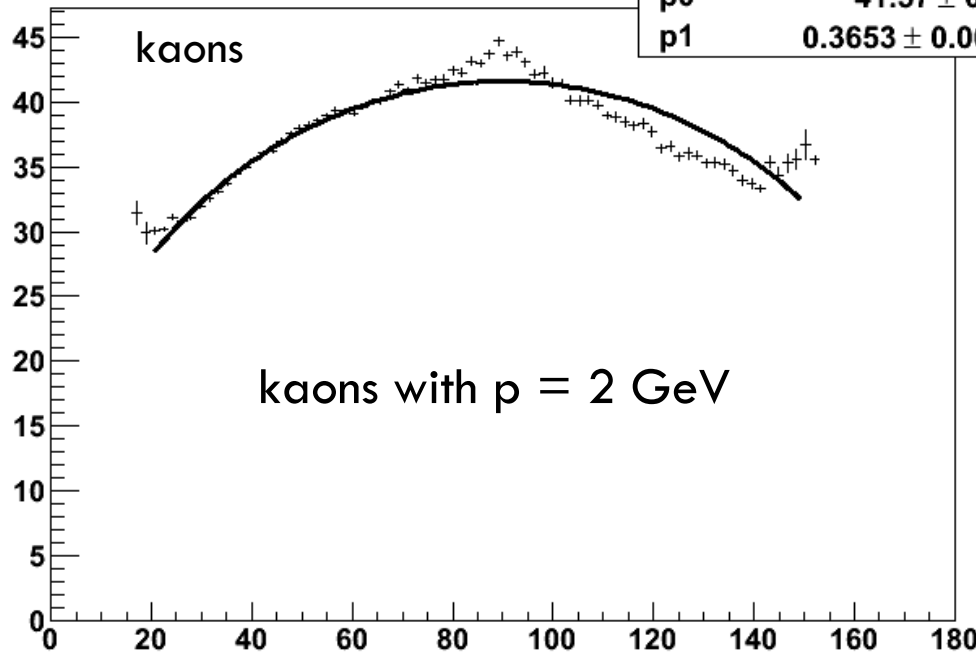

the same for kaons: good agreement with pions

$$f(\theta) = p_0(\sin \theta)^{p_1}$$

dedxErr*sqrt(nsampdch/40) vs θ (p in [1.9,2.1])		if
		1194 / 70
p0	41.57 ± 0.05	
p1	0.3653 ± 0.0027	

$$\longleftrightarrow p_1 = -\gamma$$

$\rightarrow \gamma = -0.37$
(it was set to -0.5)

Note 1: the distribution is significantly fwd-bwd asymmetric

Note 2: the normalization by $\sqrt{N_{\text{hit}}}$ has *almost* removed the peaks in the fwd/bwd regions

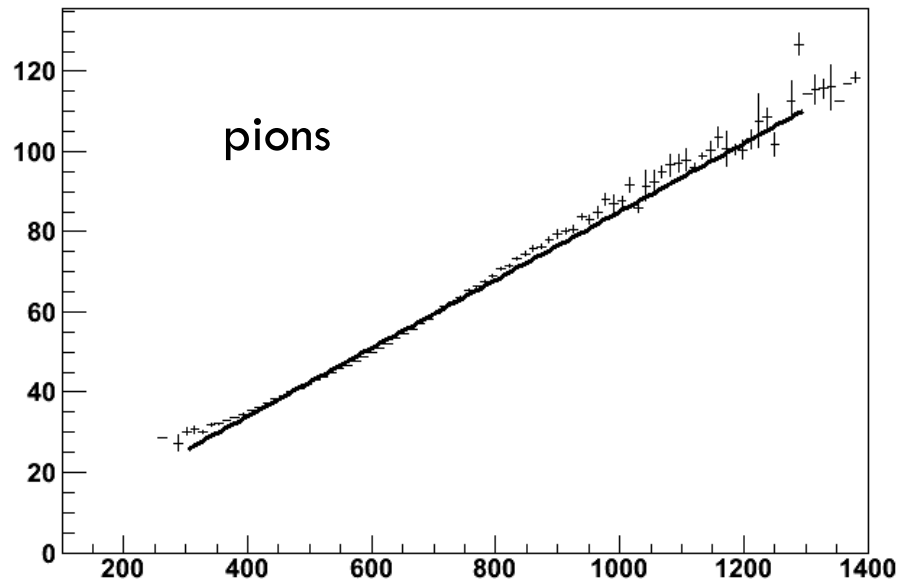

$\sigma(dE/dx)$ vs dE/dx (pions)

Then I “measure” α and β :

$$\sigma\left(\frac{dE}{dx}\right) = \alpha\left(\frac{dE}{dx}\right)^\beta dx^\gamma$$

I take $\sigma(dE/dx)$ vs dE/dx after having normalized $\sigma(dE/dx)$ by $\sqrt{N_{\text{hit}}}/dx^\gamma$

dedxErr*sqrt(nsampdch/40)*sin(theta)^(-|a|) vs dE/dx

□

Not a real fit: I consider $y(x)=\text{par0}*x$ and find the value of par0 that ‘fits’ reasonably well. If such value exists, then it means that $\alpha=\text{par0}$ and $\beta=1$ is a reasonable assumption

In the plot on the left:

$$\alpha=0.085$$

$$\beta=1$$

$\sigma(dE/dx)$ vs dE/dx (kaons)

same for kaons

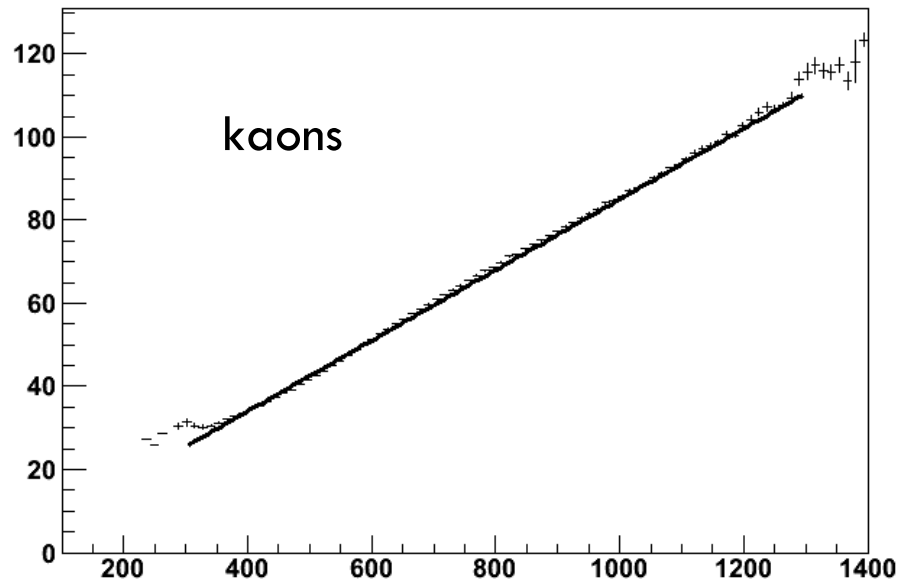

In the plot below:

$\alpha=0.085$

$\beta=1$

$$\sigma\left(\frac{dE}{dx}\right) = \alpha\left(\frac{dE}{dx}\right)^\beta dx^\gamma$$

dedxErr*sqrt(nsampdch/40)*sin(theta)^(-|a|) vs dE/dx

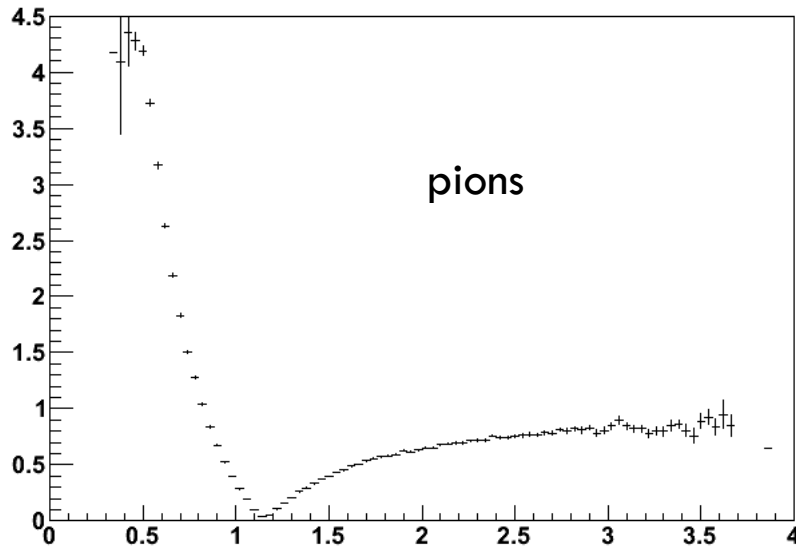

good agreement between
pions and kaons

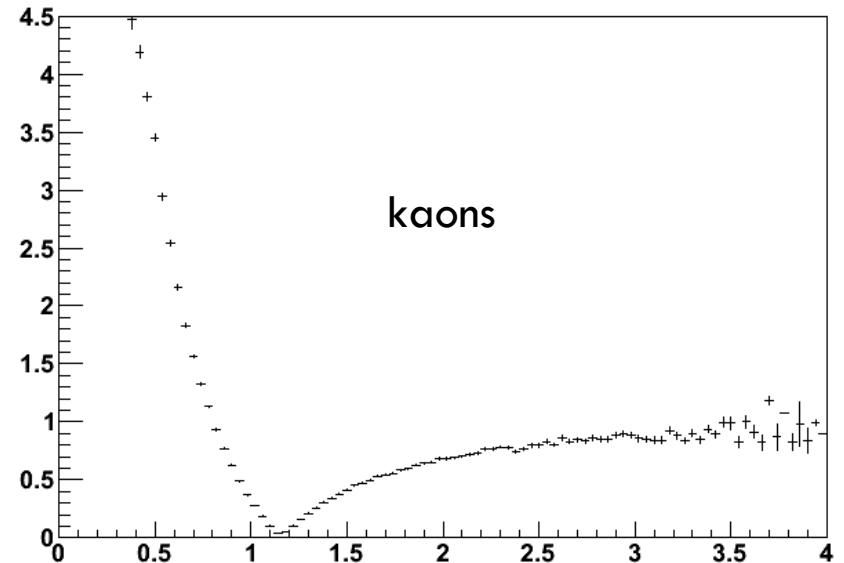

Kaon-pion separation with dE/dx

$$\theta = 90^\circ$$

(dE/dx_pi-dE/dx_K)/dedxErr vs pdch $\theta=90\text{deg}$

(dE/dx_pi-dE/dx_K)/dedxErr vs pdch $\theta=90\text{deg}$

$$\text{separation} = [dE/dx_{(\text{exp pion})} - dE/dx_{(\text{exp kaon})}] / \sigma(dE/dx)$$

Kaon-pion separation with dE/dx

$$\theta = 30^\circ$$

(dE/dx_pi-dE/dx_K)/dedxErr vs pdch $\theta=30\text{deg}$

(dE/dx_pi-dE/dx_K)/dedxErr vs pdch $\theta=30\text{deg}$

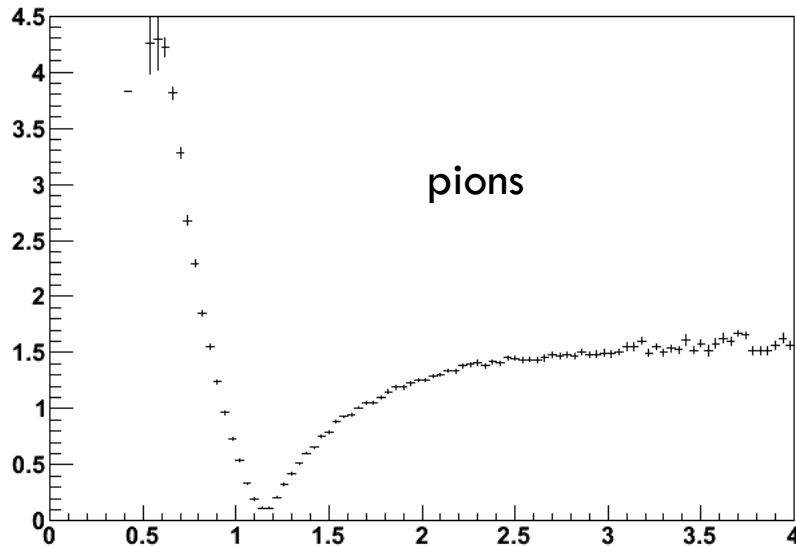

$$\text{separation} = [dE/dx_{(\text{exp pion})} - dE/dx_{(\text{exp kaon})}] / \sigma(dE/dx)$$

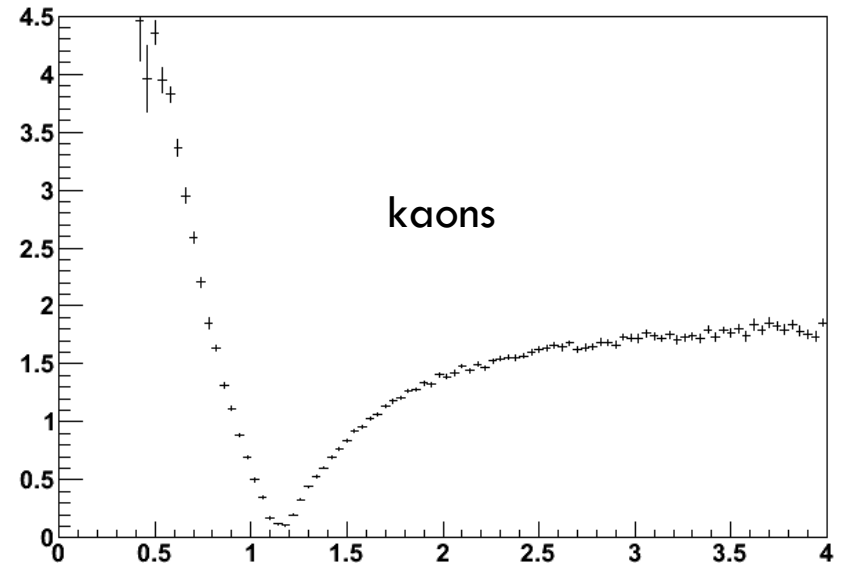

Kaon-pion separation with dE/dx

θ in $[20^\circ, 24^\circ]$ (region not covered by DIRC)

(dE/dx_pi-dE/dx_K)/dedxErr vs pdch $\theta=[20,24]$ deg

(dE/dx_pi-dE/dx_K)/dedxErr vs pdch $\theta=[20,24]$ deg

$$\text{separation} = [dE/dx_{(\text{exp pion})} - dE/dx_{(\text{exp kaon})}] / \sigma(dE/dx)$$

Summary

- Interesting feature of nDCH hits vs theta observed in Babar data
 - ▣ now implemented in FastSim for the Babar config.
 - ▣ should we adopt the same for the baseline SuperB configuration?
- Used the Babar data to tune the Babar drift chamber dE/dx in FastSim
 - ▣ should we adopt the same parameters for the baseline SuperB configuration?

Further discussion at the FastSim session tomorrow at 16:00
