

Tuning MC and DATA for VETO

F. Oliva on behalf of the PADME Lecce group

OUTLINE

A first try to calculate the yield of Bremsstrahlung was done but MC and DATA were not in agreement.

Maybe a step too far

A step back was needed
to understand better MC for PVeto and consequently
the DATA to allow the tuning DATA/MC

Step 0

Understand energy release in Veto for MC

Single Positron simulations

Step 1

MC simulation from Target and from BeW

Step 2

DATA

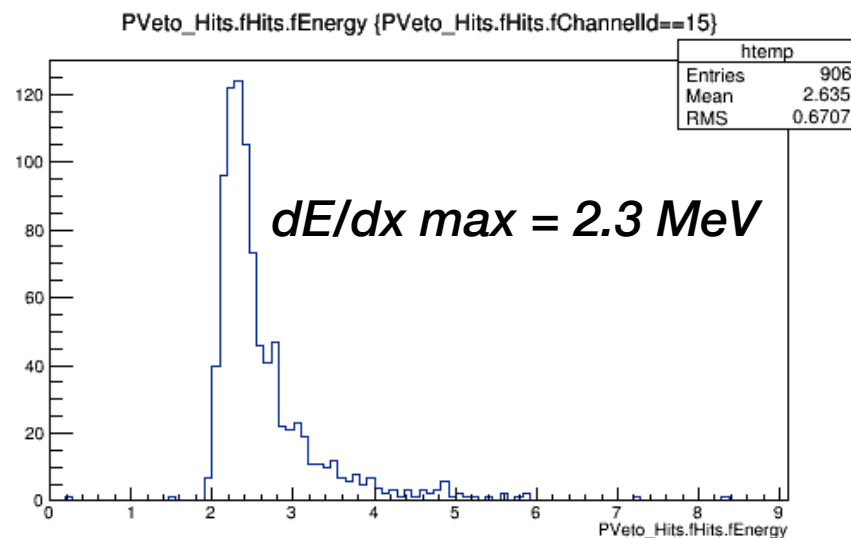

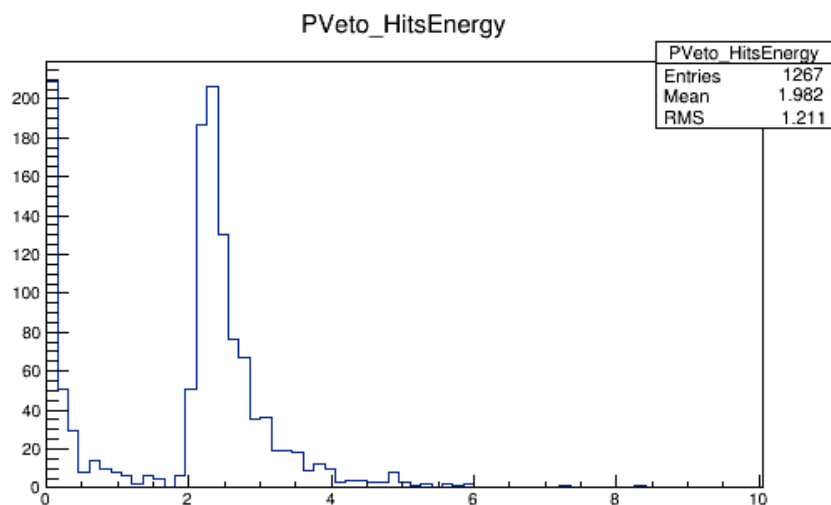

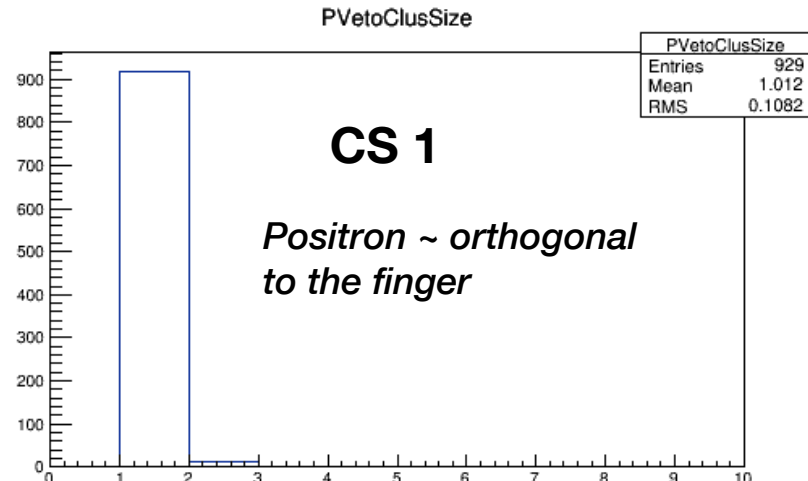

Step 3

Comparison DATA/MC and tuning

Step 0 - Single Positron MC

What is the energy release at most in Veto?

$E=50$ MeV

A mip releases in the finger ~2.3 MeV at most

Single Positron MC

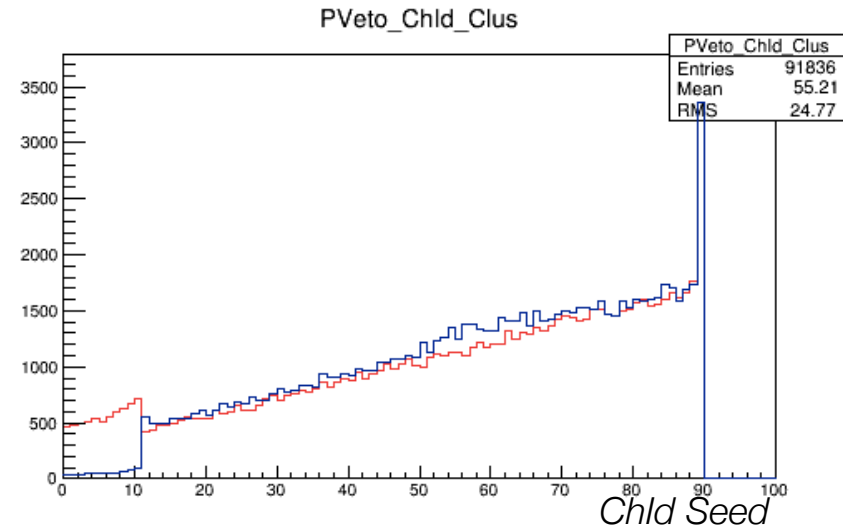

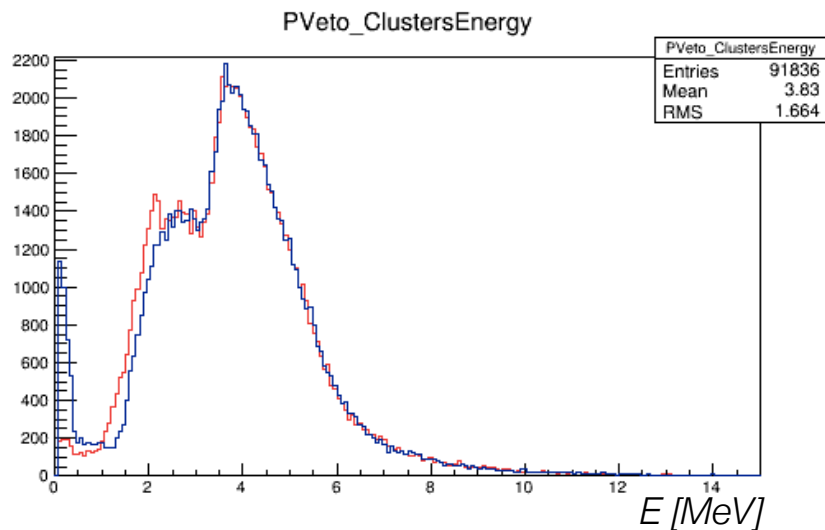

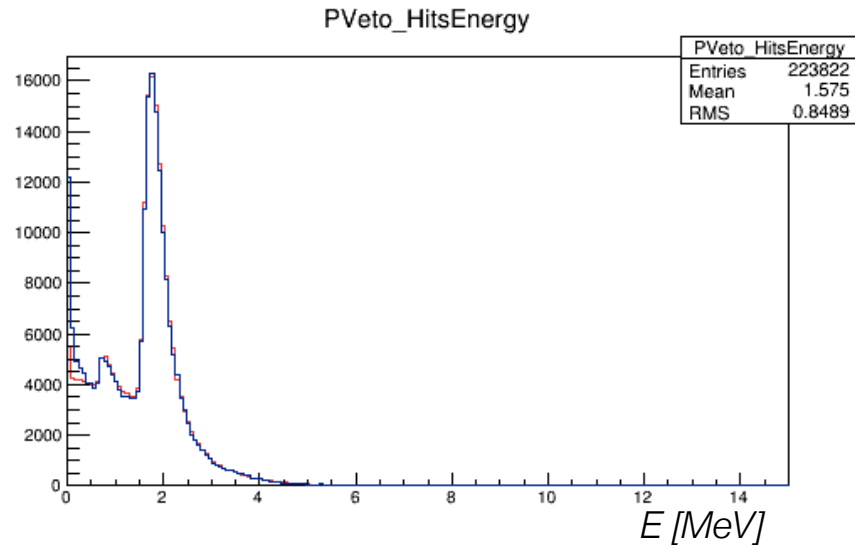

Single Positron Momentum 0.0001 MeV

Momentum Spread Uniform distribution [0, 500] MeV → To hit every single finger in the PVeto with a unique simulation

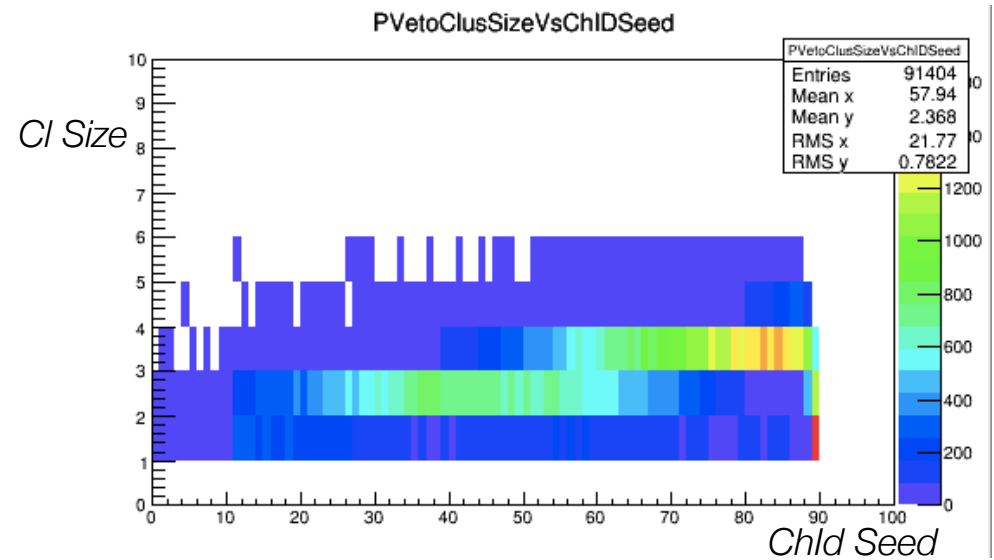

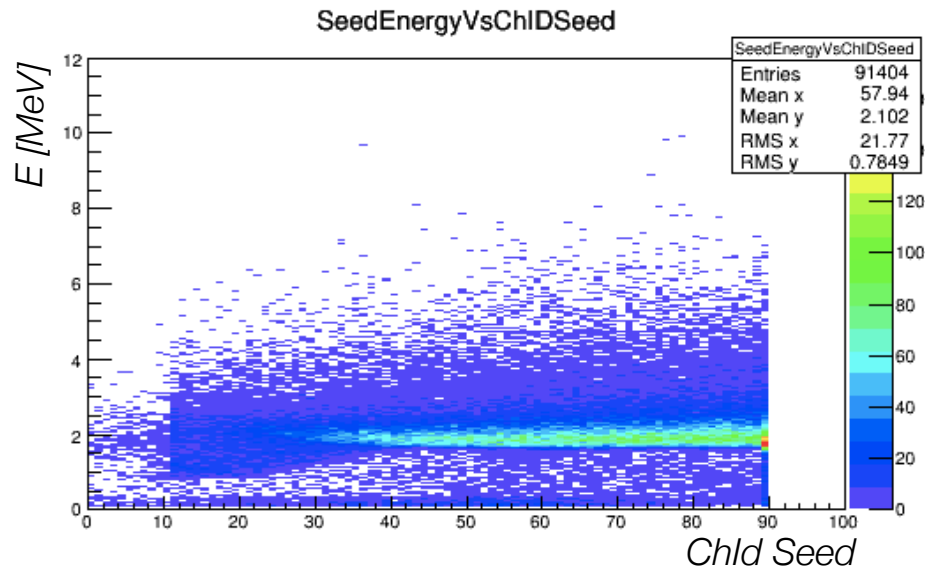

Low Clusterization Thrs Thr Seed 0.1/Hit 0.1, deltaTimeClusters 1ns

100 k events

VC on / VC off

...focusing on Vacuum Chamber on

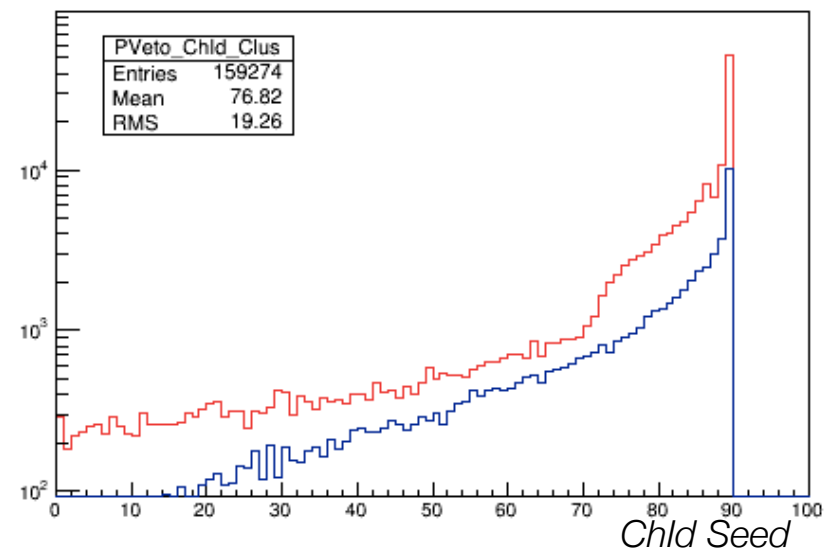

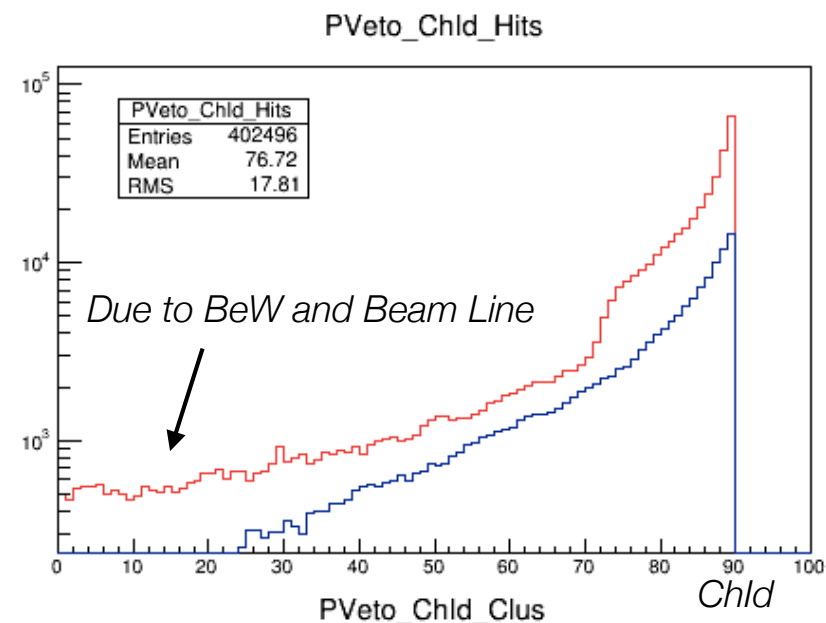

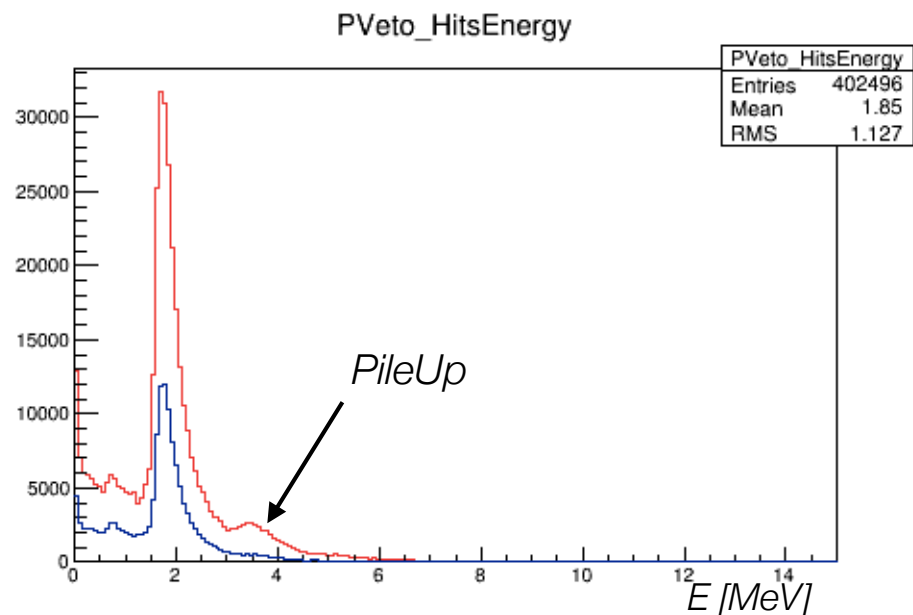

Step 1

MCs comparison

MC 23 k POT, beamFromBeW 250 ns bunch length digi 1ns

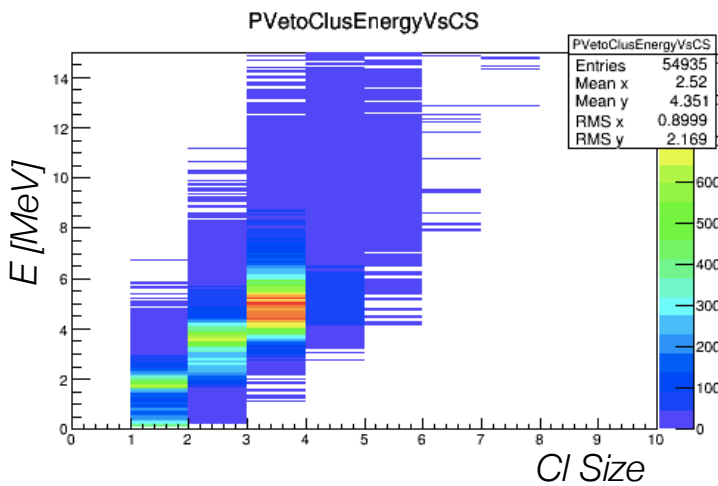

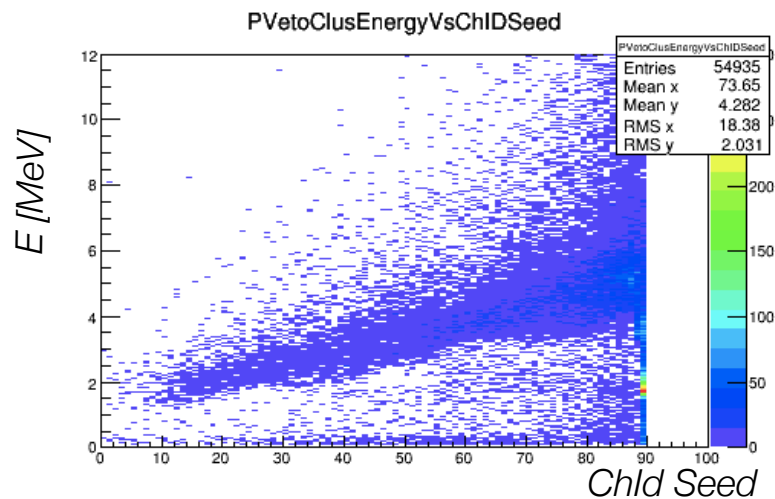

1 k events

MC 23 k POT, beamFromTarget 250 ns bunch length digi 1ns

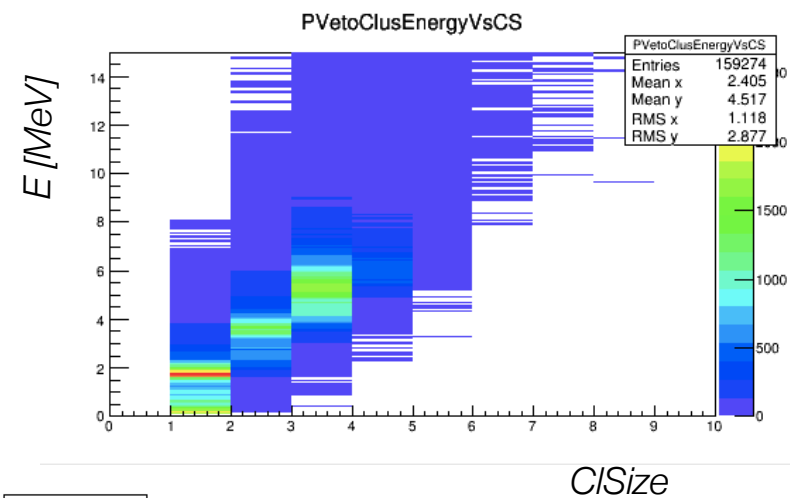

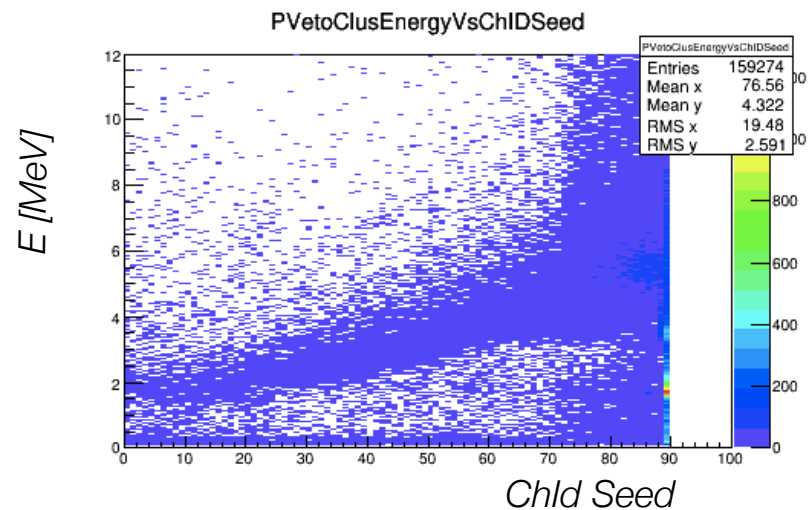

Low Clusterization Thrs Thr Seed 0.1/Hit 0.1, deltaTimeClusters 1ns

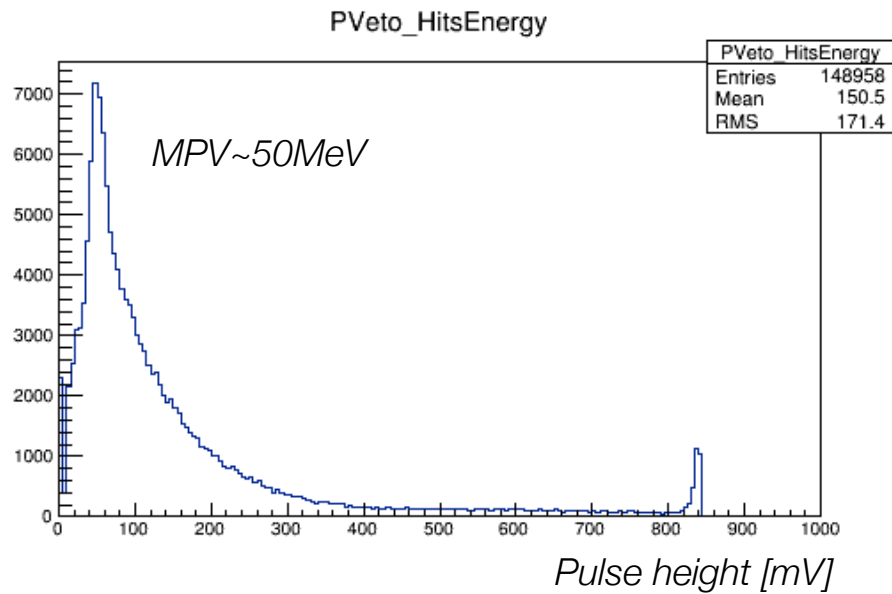

Positron beam in front of TARGET

Positron beam in front of BeW

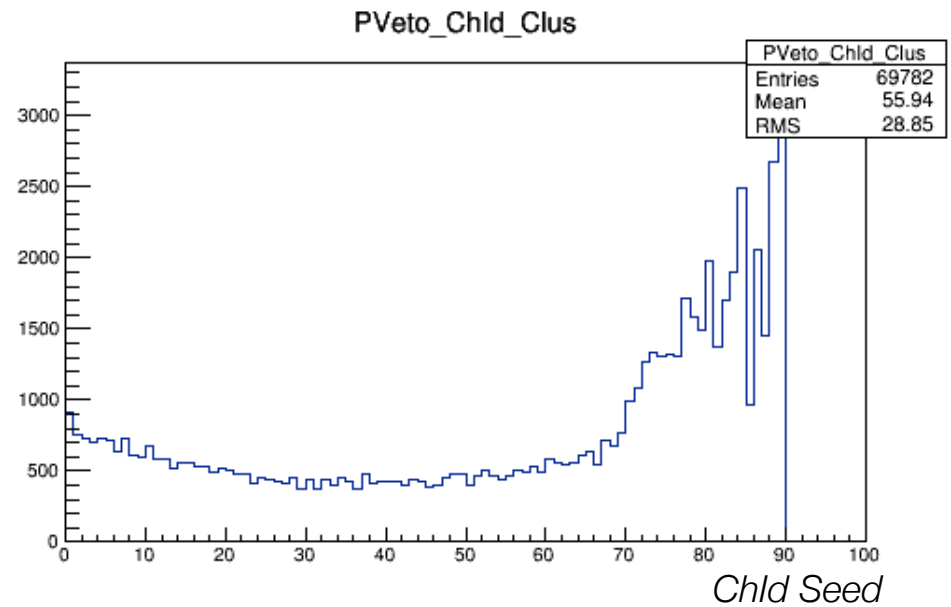

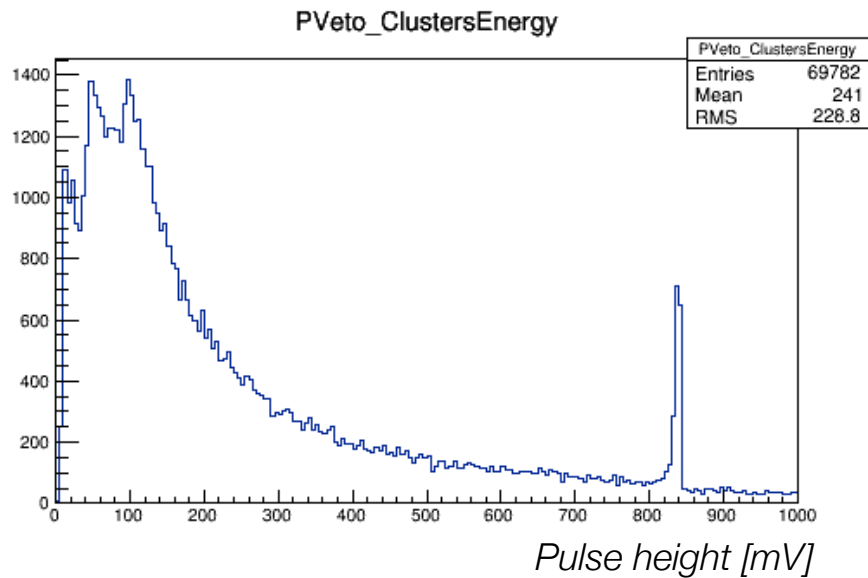

Thr Hit 2.5mV / Thr Seed 2.5 mV *DeltaTimeClusters 5ns*

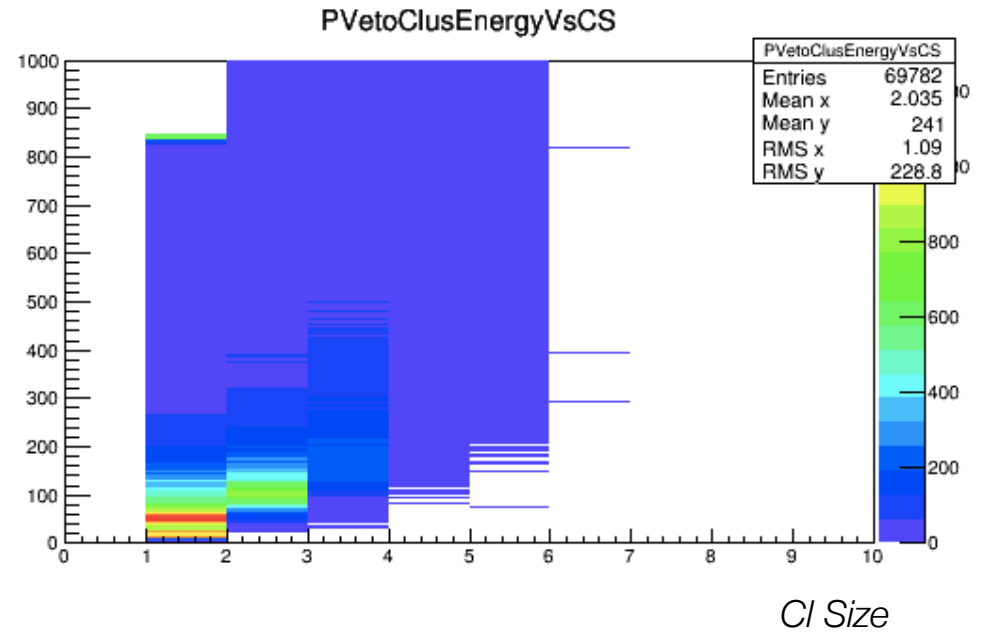

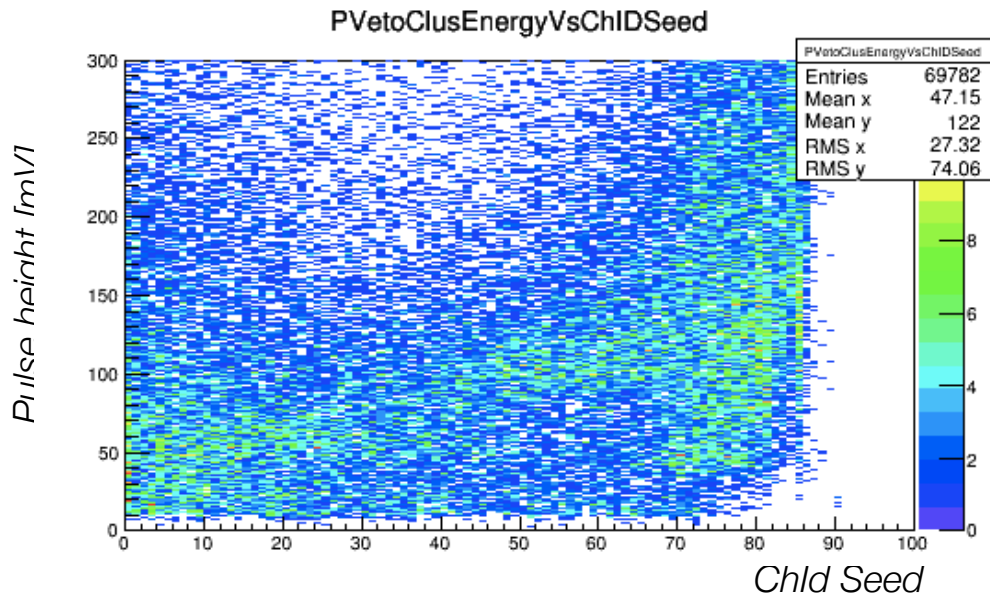

The energy associated to the hit for DATA corresponds to the pulse height of the signal. For the comparison with the MC a conversion factor is needed.

A mip in MC releases ~2 MeV in mC that corresponds to the MPV value of ~50 mV for DATA :

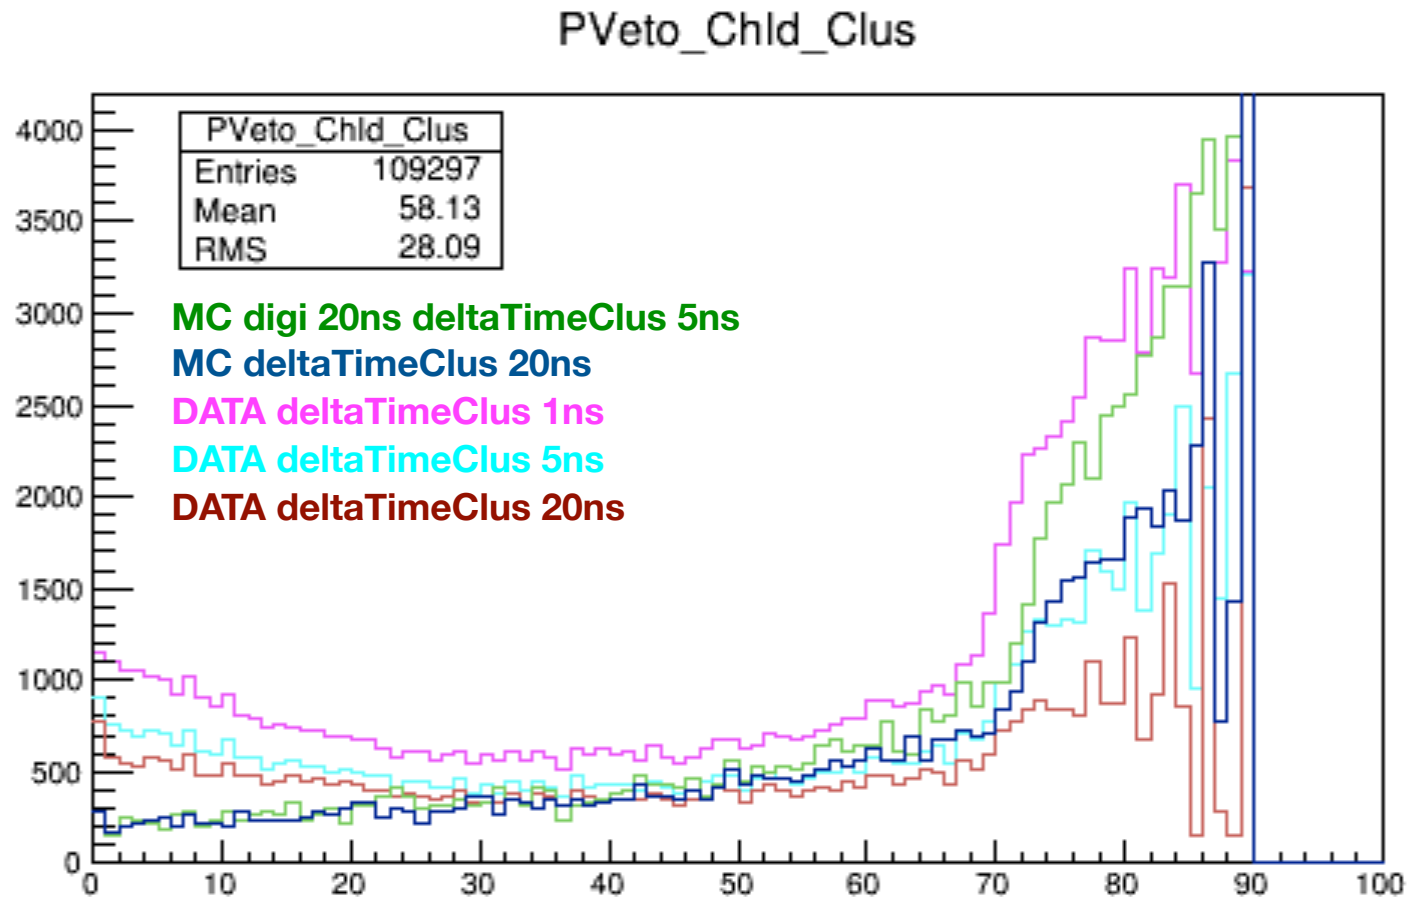

$$\text{DATA Energy [MeV]} = \text{Pulse Height} / (25\text{mV/MeV})$$

Occupancy varying deltaTime Clusters for MC and DATA

The delta time cluster was enlarged for MC to emulate the time integration of the Veto front-end response.

A change in the MC digi time is maybe needed to compare MC and DATA. At the moment the digi time for MC is set at 5 ns in the develop.

Comparison between DATA and MC production with digi time = 20 ns

Step 3

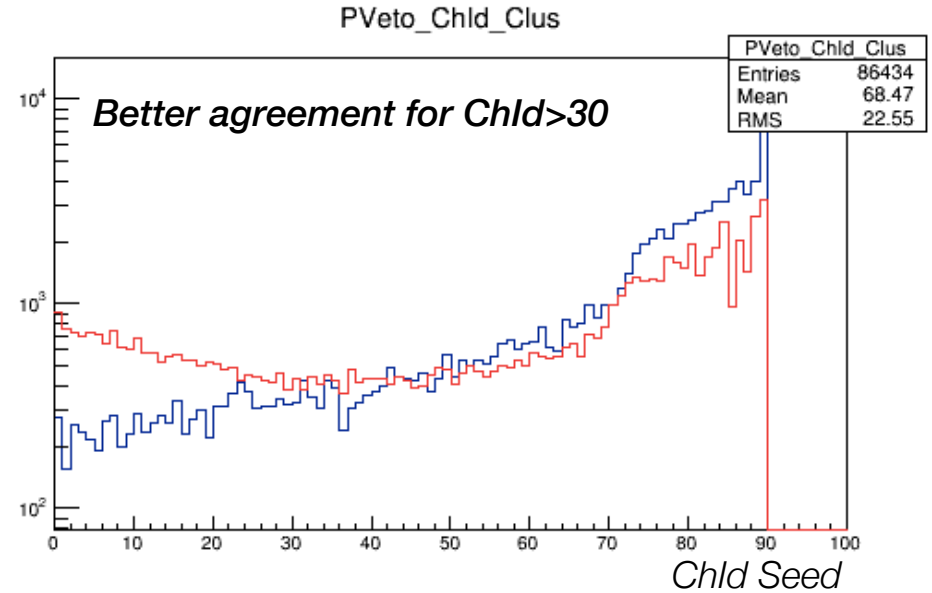

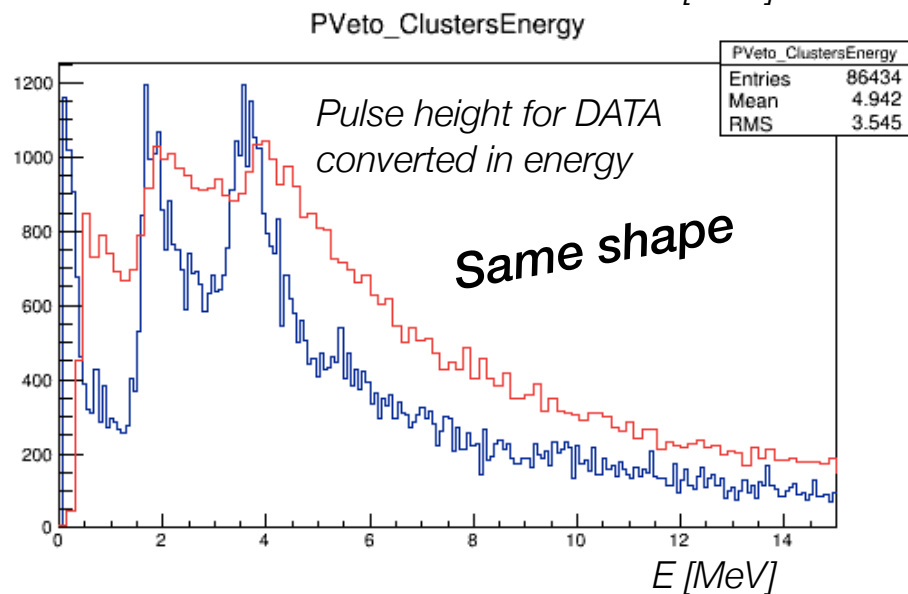

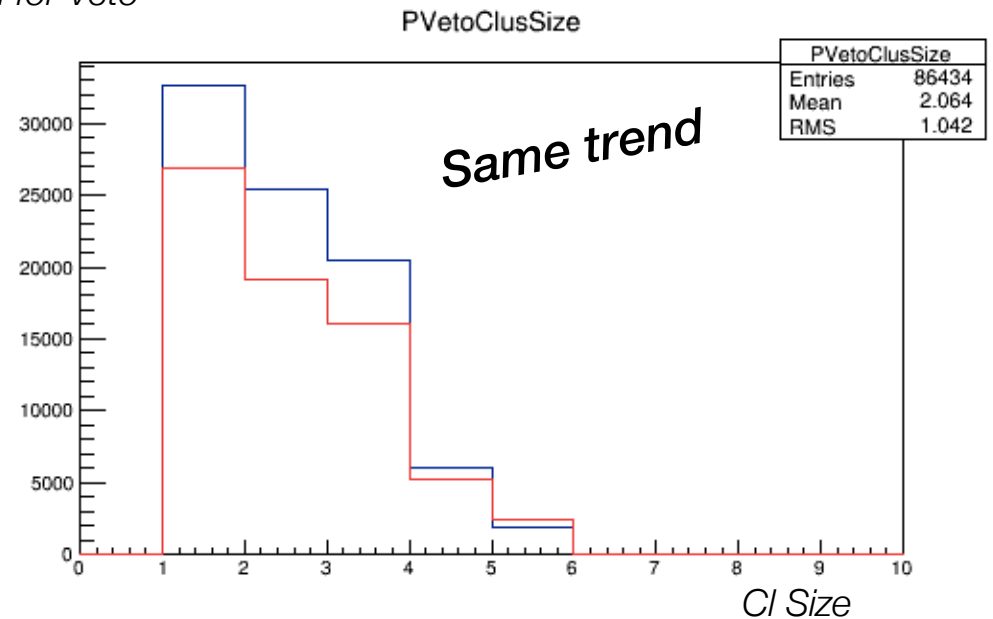

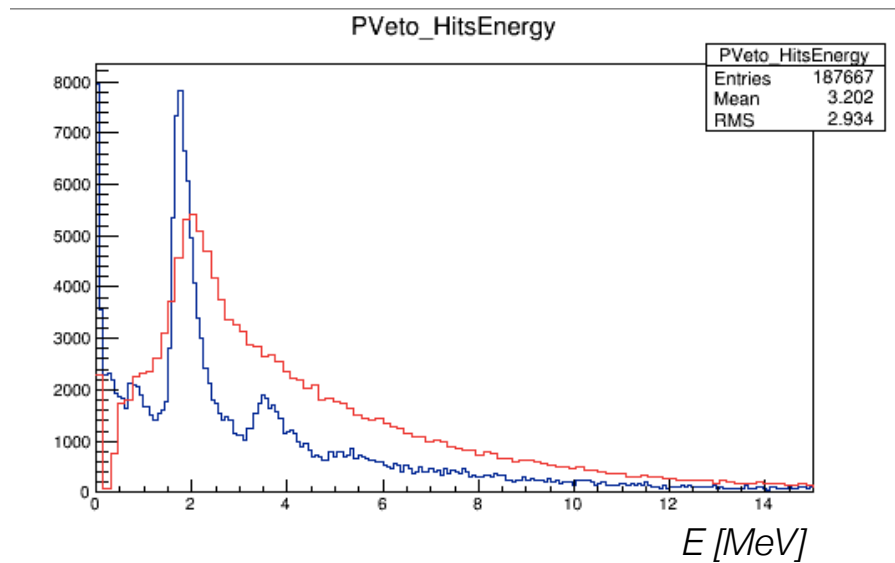

MC digi 20 ns delta cluster time 5ns / DATA delta cluster time 5ns

MC DATA comparison

First try

1 k events

Emulating the rising time of the signal for Veto

Conclusion

- *A comparison between MC vs DATA for veto at hits and clusters level is underway in order to understand occupancy and rate of beam background and bremsstrahlung.*
- *Simulated single positrons with flat energy distributions from 0-500 MeV allowed to understand hit and cluster energy spectrum and cluster size along z:*
 - *linear increase of energy peak and cluster size with z*
 - *a positron shadow for Veto from chld 1 to 10 is clearly visible for low energy single positrons due to fringe field and vacuum chamber wall.*
- *Simulated sample of 23000 positrons per bunch without and with the beamline+BeW clearly show that the positron rate on the Veto is dominated by the beam-line+BeW material and not from bremsstrahlung from target.*
 - *The simulation of the beamline+BeW show a positron shadow for Veto from chld 1 to 10 with significant rate and flat energy spectrum*
 - *The simulation of the beamline+BeW show a sharp increase of rate for chld 70*
- *July data showed an energy spectrum, a cluster size and an occupancy semi-qualitative similar to MC only after hit digitization and clusterization parameters tuning.*
- *Tuning between MC and DATA is still underway.*
