

$K^- NN$ -oriented phenomenology of kaonic atoms and future experiments

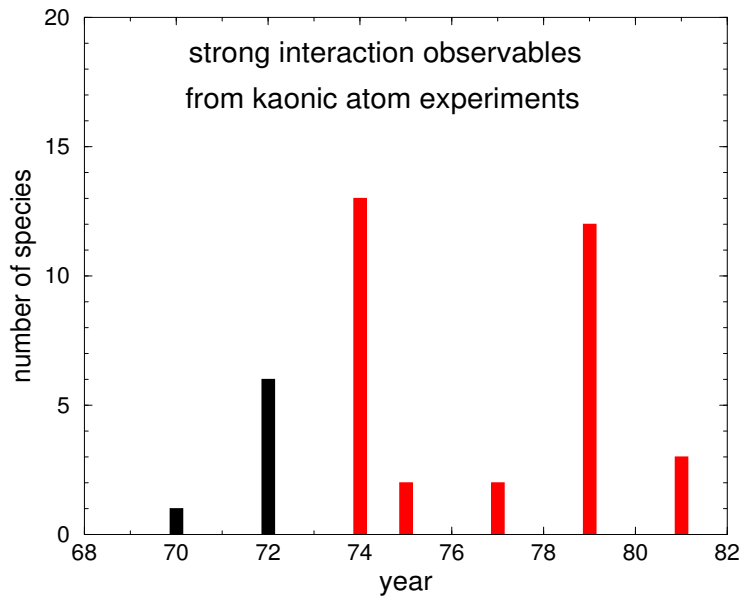

E. Friedman

Racah Institute of Physics, Hebrew University,
Jerusalem

DAΦNE zoom meeting, 25-26 February 2021

Outline

- Experimental background
- Evolution of analyses
- $K^- NN$ -guided phenomenology
- What next?

The simplest optical potential:

$$2\mu V_{\text{opt}}(r) = -4\pi(1 + \frac{A-1}{A} \frac{\mu}{M}) \{ b_0[\rho_n(r) + \rho_p(r)] + b_1[\rho_n(r) - \rho_p(r)] \}.$$

ρ_n and ρ_p are the neutron and proton density distributions, M is the mass of the nucleon, μ is the reduced mass.

Global fits to kaonic atom data usually cannot determine b_1 .

Good fits ($\chi^2=129$ for 65 points) lead to

$$b_0 = 0.63 \pm 0.06 + i (0.89 \pm 0.05) \text{ fm},$$

which in the impulse approximation is minus the scattering amplitude at threshold.

From phase-shifts $b_0 = -0.15 + i 0.62 \text{ fm}$.

The low-density limit is not respected. (1993)

Early attempts to use chiral amplitudes

Ramos & Oset, NPA 671 (2000) 481

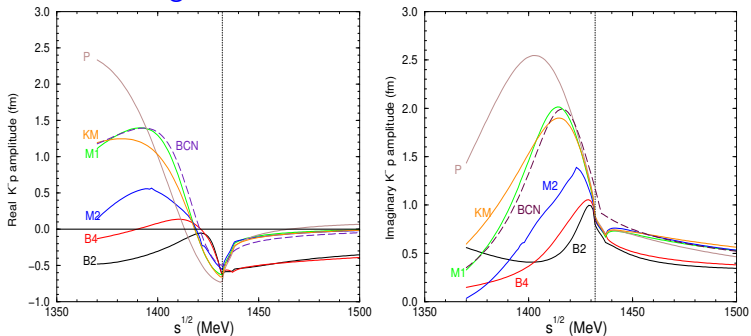

Baca et al., NPA 673 (2000) 335

Cieply et al., NPA 696 (2001) 173

- Poor agreement with data ($\chi^2(65)=300$)
- Reduced χ^2 to 200 with typical 50% rescaling
- $\chi^2=130$ by adding a $t\rho$ term with NEGATIVE absorption

Something is missing!

Seven chiral K^-N models constrained by fits to near-threshold data, including the SIDDHARTA result for K^-H at threshold

For attractive potentials the energy \sqrt{s} is below threshold within the nuclear medium.

In addition there are corrections due to Pauli correlations.

The algorithm performs averaging over subthreshold energies.

PLB 702 (2011) 402; PRC 84 (2011) 045206; NPA 899 (2013) 60;
EPJ Web of Conferences 81 (2014) 01018; NPA 959 (2017);
(partial list).

χ^2 for 65 kaonic atoms data points from optical potentials based only on single-nucleon amplitudes, including subthreshold energies.

model	B2	B4	M1	M2	P	KM	BCN
$\chi^2(65)$	1174	2358	2544	3548	2300	1806	2829

Not fits!

Fits to 65 kaonic atoms data points when single-nucleon amplitudes are supplemented by a $B_0(\rho/\rho_0)^\alpha$ amplitude with fixed α compatible with its best-fit value. B_0 in units of fm.

model	BCN	M1	M2	P	KM
α	1.0	0.3	1.0	1.0	1.0
$\text{Re}B_0$	-1.6 ± 0.3	0.3 ± 0.1	2.1 ± 0.2	-1.3 ± 0.2	-0.9 ± 0.2
$\text{Im}B_0$	2.0 ± 0.3	0.8 ± 0.1	1.2 ± 0.2	1.5 ± 0.2	1.4 ± 0.2
$\chi^2(65)$	112	121	109	125	123

Is it necessary to go subthreshold?

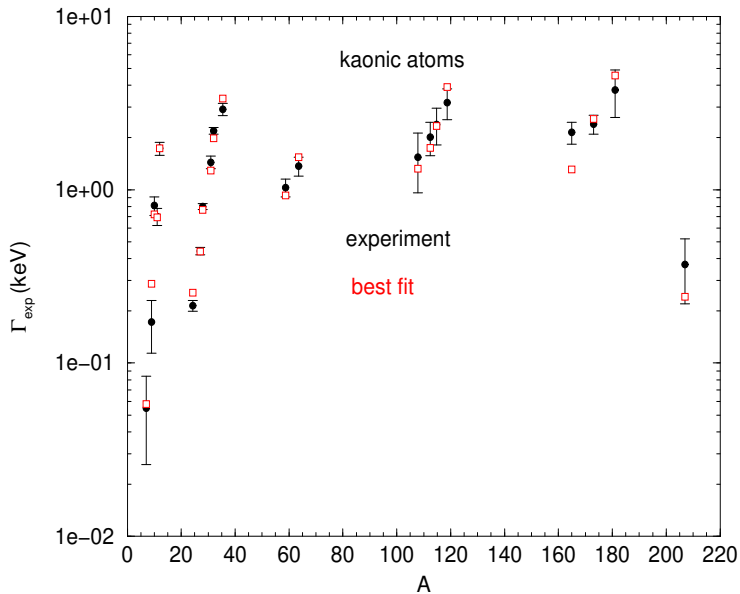

Example for KM, when $\delta\sqrt{s}=0$:

$\alpha = 1.0$, $\text{Re}B_0 = -1.8 \pm 0.1$, $\text{Im}B_0 = -1.1 \pm 0.1$, $\chi^2(65) = 139$

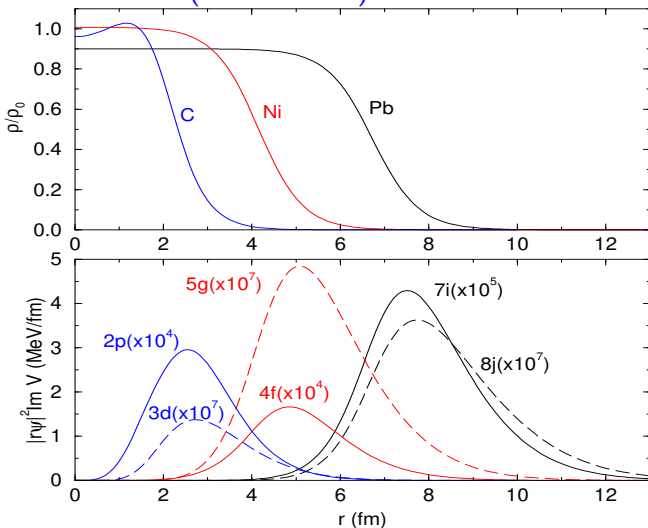

Negative $\text{Im}B_0$ and/or significantly larger χ^2 obtained for all seven models when taken on threshold.

Similar problems when ignoring Pauli correlations.

Example of global fit to kaonic atoms data, $L=1\dots 6$

Kaonic atoms overlaps for 'lower' (solid curves) and 'upper' (dashed curve) states.

It is an *atomic-nuclear* system!

The level width Γ is obtained from the eigenvalue $E_{K^-} - i\Gamma/2$ when solving the Klein-Gordon equation with an optical potential, ($E_{K^-} = m_{K^-} - B_{K^-}$). It is also related to the imaginary part of the potential by the overlap integral of $\text{Im } V_{K^-}$ and $|\psi|^2$,

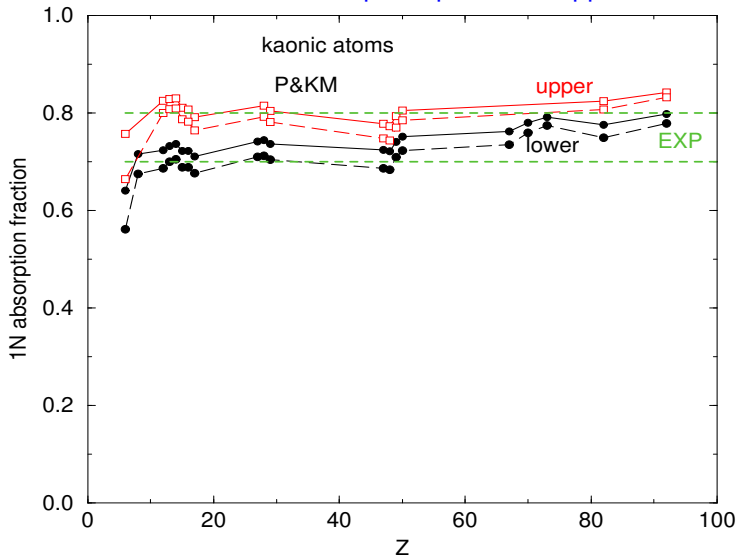

$$\Gamma = -2 \frac{\int \text{Im } V_{K^-} |\psi|^2 d\vec{r}}{\int [1 - (B_{K^-} + V_C)/\mu_K] |\psi|^2 d\vec{r}}$$

where B_{K^-} , V_C and μ_K are the K^- binding energy, Coulomb potential and reduced mass, respectively, and ψ is the K^- wave function of the particular state concerned.

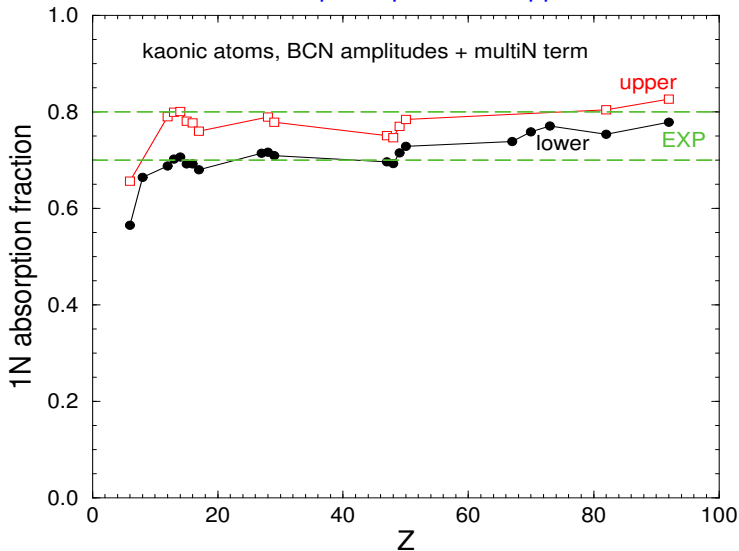

Focusing on the multinucleon absorption

When the *best fit* optical potential is $V_{K^-}^{(1)} + V_{K^-}^{(2)}$, the sum of a single-nucleon part and a multinucleon part, it is possible to calculate the fraction of single-nucleon absorptions, separately for any nucleus and for any specific kaonic atom state.

Fraction of single-nucleon absorption for amplitudes **P** and **KM**.
Solid circles for lower states, open squares for upper states.

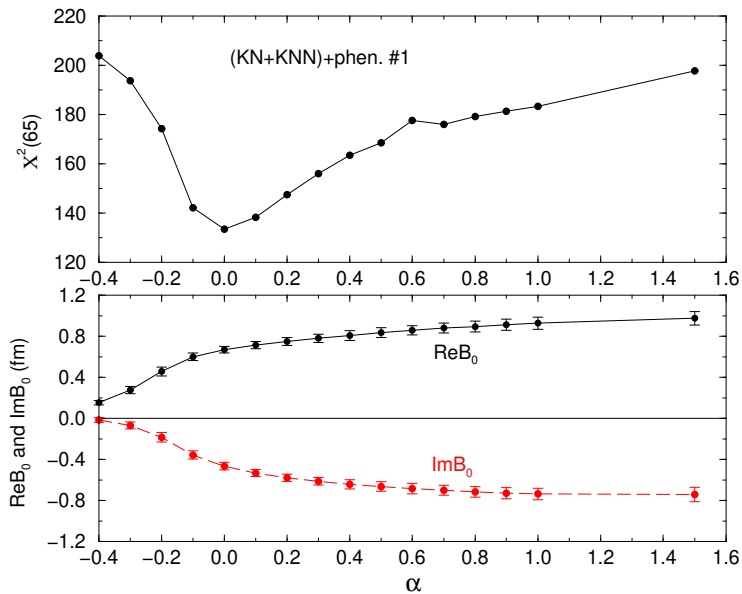

Fraction of single-nucleon absorption for amplitudes **BCN**. Solid circles for lower states, open squares for upper states.

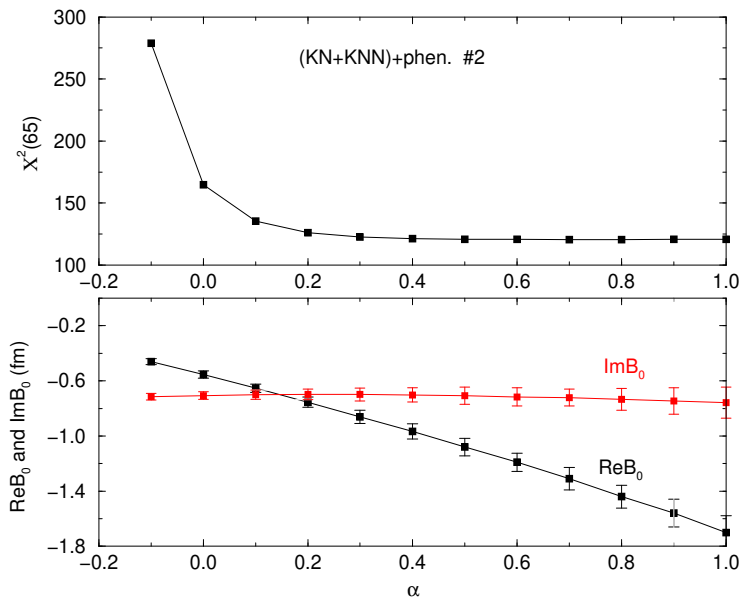

Interim Summary

phenomenology \rightarrow (threshold single N +phen.) \rightarrow
 (subthreshold $1N$ +phen.) \rightarrow (sub. $1N+2N$ +phen.)

model	$\chi^2(65)$	comments
phen.	130	-
thresh. $1N$ +phen.	300	$\text{Im}B_0 < 0$
subthresh. $1N$	2800	-
subthresh. $1N$ +phen.	129	$\text{Im}B_0 > 0$
subthresh. $1N+2N$	338	-
subthresh. $1N+2N$ +phen.	134	yet incomplete

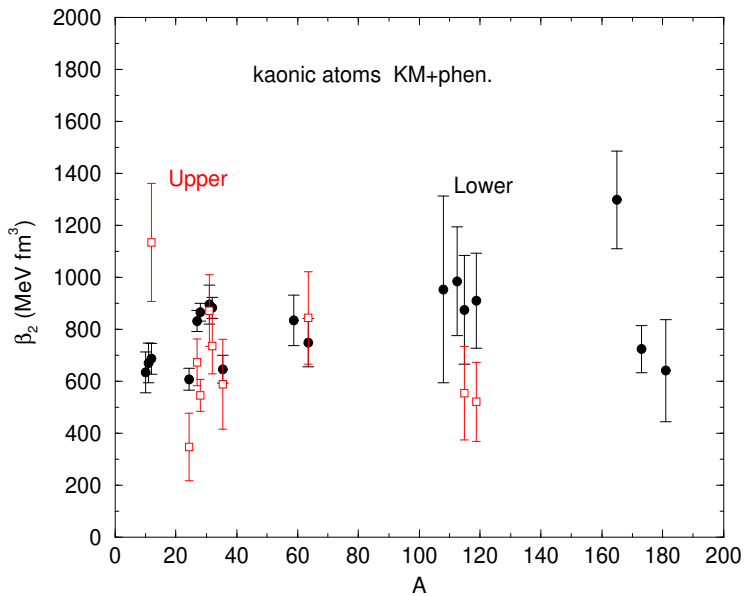

The simplest model of absorption on two nucleons calls for an imaginary part of the optical potential that is proportional to ρ^2 $\Gamma_{NN} \propto \int \rho^2 |\psi|^2 d\vec{r}$ where the kaonic atom wave function ψ is normalized to a volume integral of 1. Normalizing also the overlap integral with ρ^2 and normalizing on A nucleons, we define a parameter β_2 as follows

$$\Gamma_{NN} = \beta_2 \frac{A \int \rho^2 |\psi|^2 d\vec{r}}{\int \rho^2 d\vec{r}}.$$

Studies of the parameter β_2 along the periodic table could lead to insight on absorption of K^- in nuclei beyond the absorption on a single nucleon,

$$\beta_2 = \Gamma_{NN} \frac{\int \rho^2 d\vec{r}}{A \int \rho^2 |\psi|^2 d\vec{r}}$$

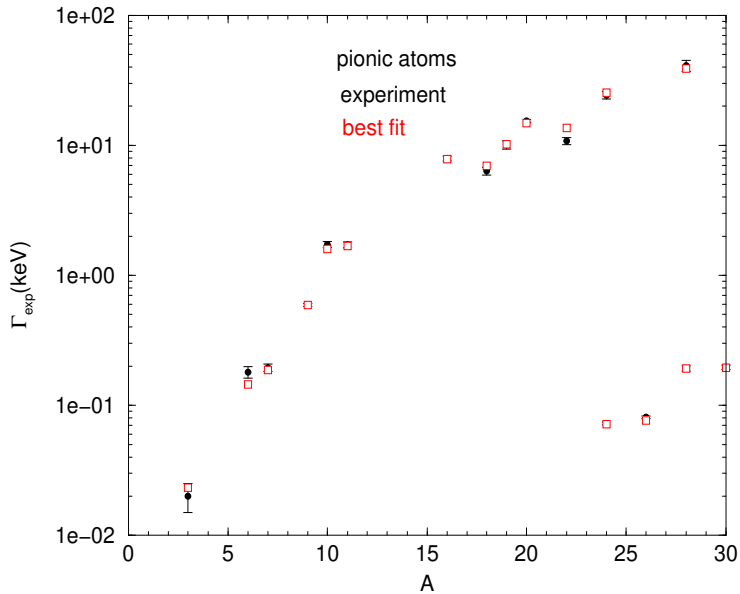

N. Barnea (Feb. 2020), private communication.

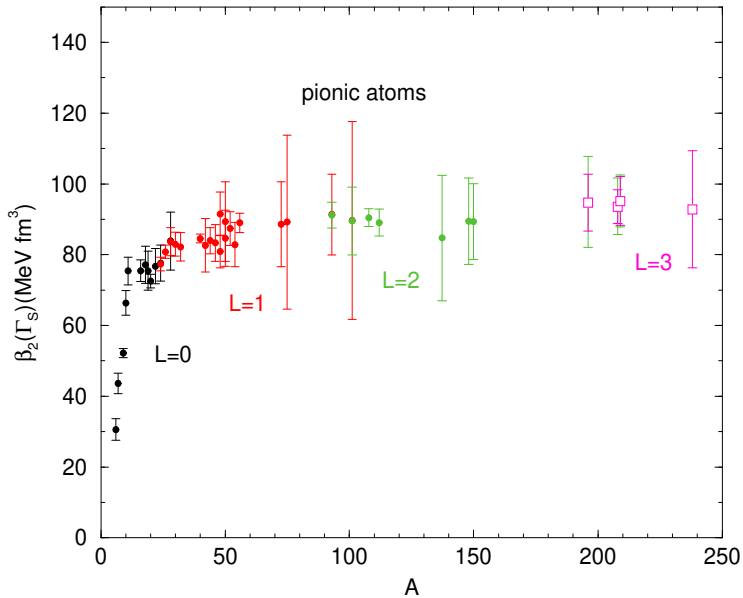

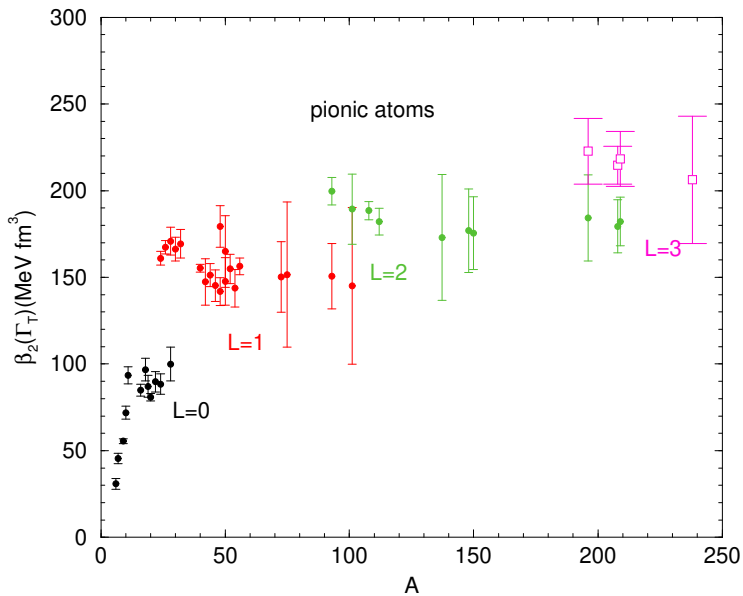

Comparing kaonic and pionic atoms

type	ImV	No. data points	No. species	L values
K^-	$1N+2N$	65	24	1-6(7)
π^-	$2N$ s+p waves	116	50	0-3

The s-wave term in the pionic potential is an analog of the $2N$ term in the kaonic potential. Easy to separate the s-wave term from the full potential. Experimental errors are generally smaller than the kaonic atom errors. Similar qualities of fits.

With

$$\beta_2 = \Gamma_{NN} \frac{\int \rho^2 d\vec{r}}{A \int \rho^2 |\psi|^2 d\vec{r}} \approx \text{constant??}$$

we note that for a K^- in an atomic s-state and Z close to 1, $|\psi|^2$ may be replaced by $|\psi(0)|^2$ and then

$$\beta_2 = \Gamma_{NN}/A |\psi(0)|^2.$$

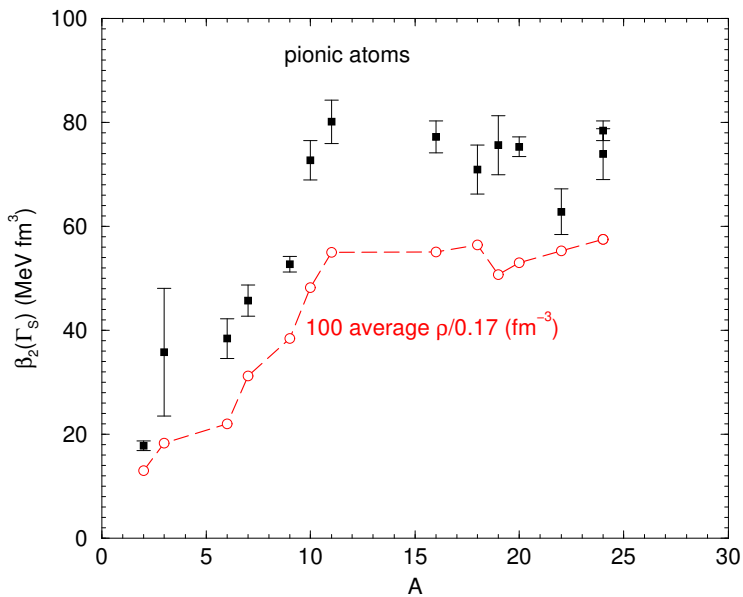

For the more general case and noting that

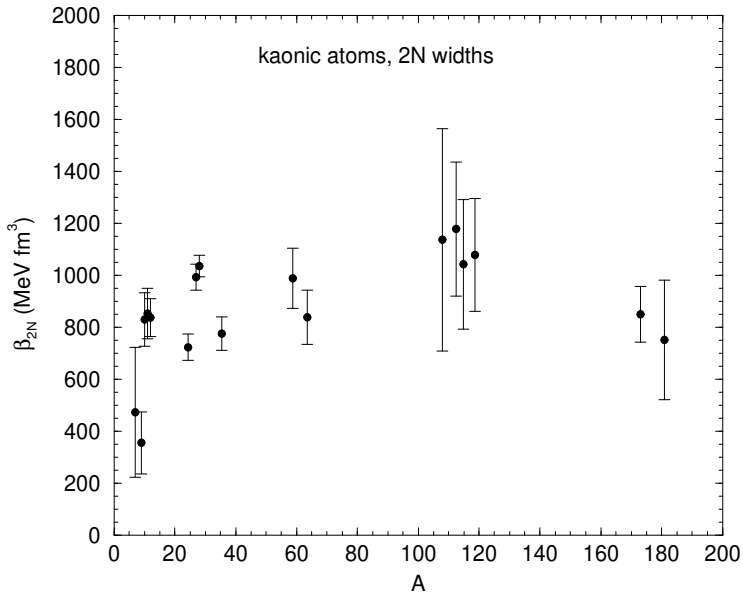

$$\int \rho^2 d\vec{r} = A \bar{\rho}$$

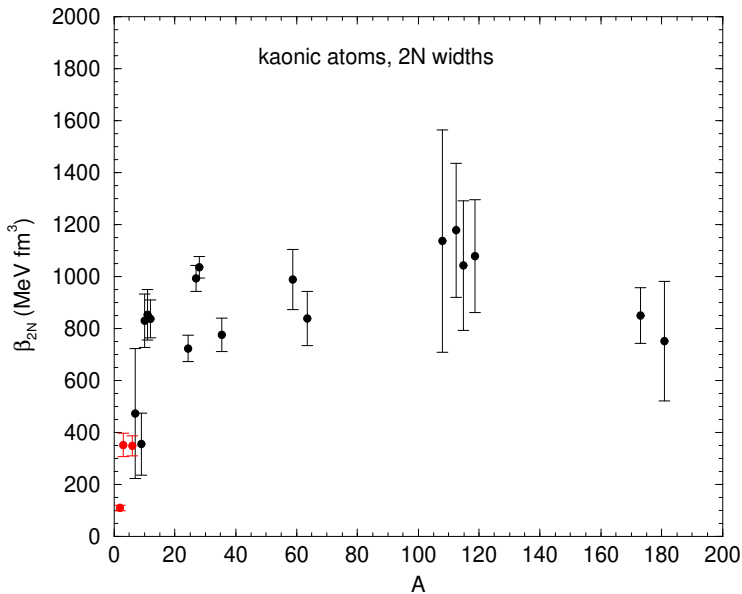

with $\bar{\rho}$ the average nuclear density, we end up with

$$\beta_2 = \frac{\bar{\rho} \Gamma_{NN}}{\int \rho^2 |\psi|^2 d\vec{r}}.$$

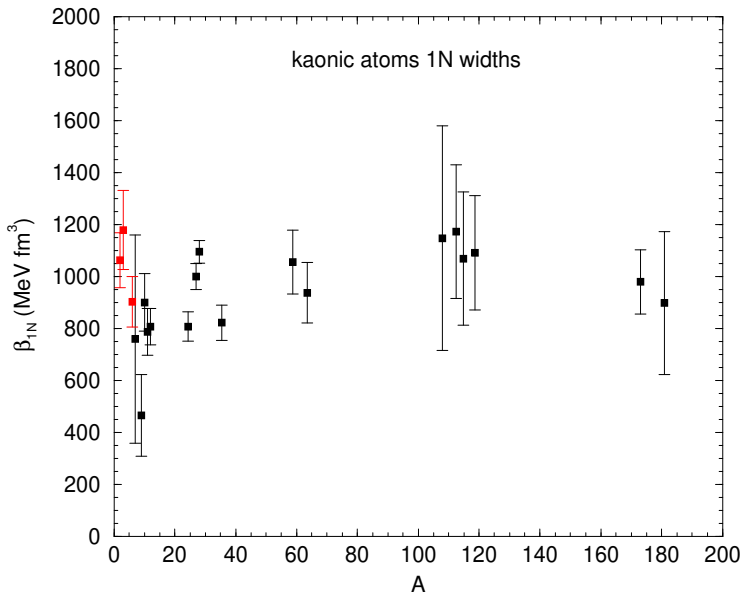

Since Γ_{NN} is approximately proportional to $\int \rho^2 |\psi|^2 d\vec{r}$ it is expected that β_2 will be proportional to the average nuclear density that increases sharply from ^3He to ^{12}C , and then assumes a rather constant value. A notable exception is ^4He with a density typical of a medium-weight nucleus.

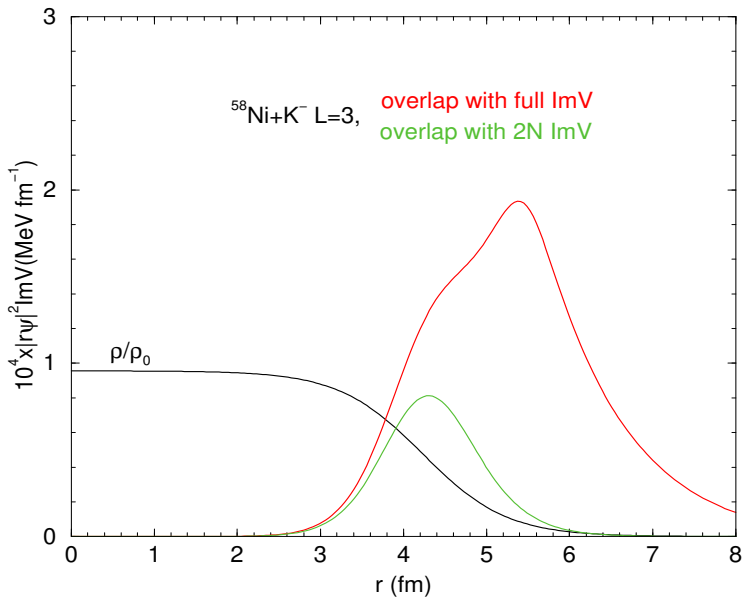

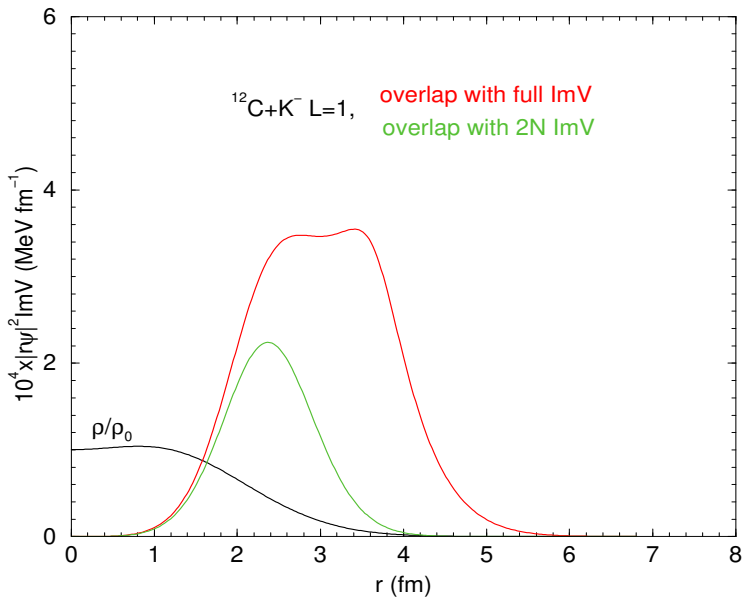

points in red are predictions of a best-fit potential

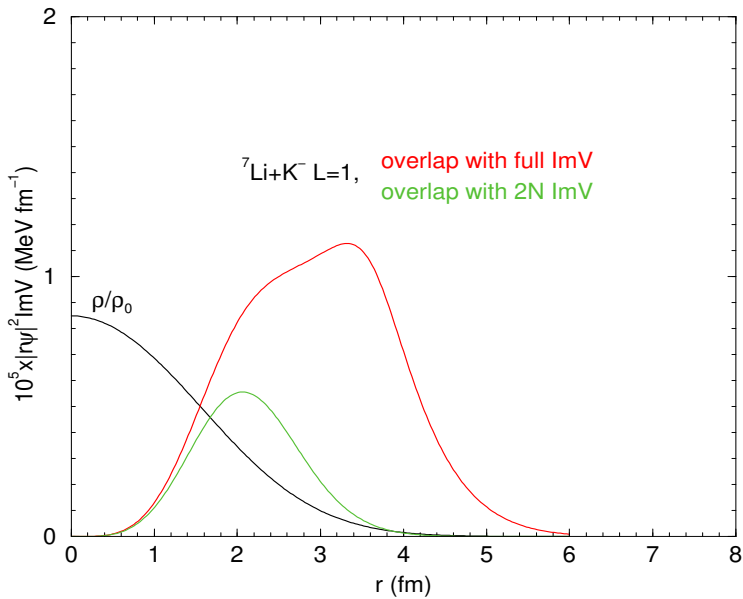

points in red are predictions of a best-fit potential

$$\rho_0 = 0.17 \text{ fm}^{-1}$$

$$\rho_0 = 0.17 \text{ fm}^{-1}$$

$$\rho_0 = 0.17 \text{ fm}^{-1}$$

Summary

- Significant progress in understanding kaonic atoms, converging on multinucleon interaction with the nucleus.
- 35-40 years old data have yielded beyond expectations.
- High quality measurements for $L=1$ kaonic states in $^3,^4\text{He}$, $^{6,7}\text{Li}$, ^9Be , $^{10,11}\text{B}$ and ^{12}C could allow for few-body approaches, connecting to the density dependence in heavier kaonic atoms.
- It is high time for new experiments.

I wish to thank Avraham Gal and Nir Barnea for meetings and discussions.
