# Why neutron capture elements?

Mg: alpha-element

Sr: neutron capture element

Bonifacio+12

# Stochastic chemical evolution models

Problem:  
Neutron capture elements present  
a spread alpha elements do not

Bonifacio+12

# Stochastic chemical evolution models

**Problem:**  
Neutron capture elements present  
a spread alpha elements do not

**Solution:**

The volumes in which the ISM is well mixed are discrete. Assuming a SNe bubble as typical volume with a low regime of star formation the IMF is not fully sampled. This promotes spread among different volumes if nucleosynthesis of the element is different among different SNe,

# Neutron stars mergers

Progenitors are rare:  
only few percent of the massive stars  
are formed in binary system which can  
produce a NS merger.

This percentage is not constrained at all  
the metallicities, the rate can be  
constrained only at the present time.

A key feature of NS merger is the delay  
between the formation of the binary  
system of neutron stars and the  
merging event.

We investigate delay of 1, 10 and  
100Myr.

Neutron star mergers (Rosswog+13)

# Neutron stars mergers

delay for the merging 1 Myr

Cescutti, Romano, Matteucci,  
Chiappini and Hirschi 2015

Results with  $\alpha=0.04$   
(NSM/SNe)

What about the impact of  
increasing the delay for the  
merging?

# Neutron star mergers

delay for the merging 100 Myr

Cescutti+15

For a delay of 100 Myr the model results are not compatible to the observational data.

Therefore, only if most of the NS mergers enriches in timescale  $< 10$  Myr, the scenario can be supported.

What about a distribution of delays?

This is not a new result, it has been shown by Argast+ 2004, Matteucci+2014, Komiya+2014... just an exception the astro-ph Shen+2014

A night sky filled with stars, with a mountain range visible at the bottom. The stars are of various colors, including blue, white, and red. The mountains are dark, with some peaks illuminated by a blue light. The overall scene is a deep blue and black, with the stars providing the primary light source.

**Other solutions?**

# Magneto Rotationally Driven SN scenario (MRD)

(Winteler+12, Nishimura+15)

The progenitors of MRD SNe are believed to be rare and possibly connected to long GRBs.

Only a small percentage of the massive stars (~1-5%)

Our results use an higher value (10%), but this percentage is not well constrained, in particular for the early Universe.

Therefore in the stochastic model not all the massive stars produce neutron capture elements.

# Magneto Rotationally Driven SN scenario (MRD) 10%

Cescutti+14

In the best model shown here the amount of r-process in each event is about 2 times the one assumed in NSM scenario

The assumed percentage of events in massive stars is higher than expected (at least at the solar metallicity), but it is reasonable to increase toward the metal poor regime  
(Woosley and Heger 2006)

# Rizzuti et al. (2021)

adopting Limongi&Chieffi18

# Rizzuti et al. (2021) adopting Limongi&Chieffi18

# Conclusions

The neutron capture elements in the Galactic halo have been produced by (at least) 2 different processes:

**A (main) r-process**, rare and able to produce all the elements up to Th with a pattern as the one observed in r-process rich stars.

**NSM are certainly the best candidate** to play this role if they have a very short time scale, or if their frequency was higher at extremely low metallicity. Other sources like MRD SNe can also play this role.

Another process more frequent and that can produce both Sr and Ba (and  $[Sr/Ba] > 0$ ) with a production that is compatible with the **s-process by rotating massive stars**. We can use this to constrain the velocity distribution of the massive stars.

CAVEAT

# The only possible answer?

Another possible solution is the production of  
+ a weak r-process  
(not able to produce all the elements up to thorium)  
+ a main r-process

Wanajo 2013, r-process production in proto neutron star wind

# Isotopic ratio for Ba

Cescutti and Chiappini (2014)

**2 stars**  
with a  $R \sim 100'000$  &  
 $S/N \sim 500$   
with UVES at VLT

“normal” value  
high  $R \sim 30'000$   
high  $S/N \sim 80-100$

The rotating massive stars scenario naturally predicts different Ba isotopic ratios in halo stars.

This prediction can be used to test our scenario.

Challenging to check these predictions

See results on HD 140283 from Magain (1995) to Gallagher+(2015)

# Synthesis of barium lines with hyperfine splitting effects

Cescutti +21

# Conclusions

Our inspection of the barium lines has found that the profiles of the lines (suffering hfs) are different in the 2 stars.

The most likely explanation is that:

HD 6268 has been polluted by an r-process source  
&  
HD 4306 by and s-process source,

**validating Cescutti&Chiappini14 results**

HR and high S/N still provide fundamental information to Galactic Archaeology, fully complementary to the amazing results coming from present and future Multiobjects spectrographs.
