Classification of Presolar SiC Grains

MS, Y, and Z Grains from AGB Stars

- $^{29}\text{Si}/^{28}\text{Si}$: a proxy of stellar metallicity
→ Y and Z grains from **lower metallicity stars** than MS grains

- $^{30}\text{Si}/^{28}\text{Si}$: a proxy of s-process efficiency
→ **s-process efficiency** follows the order of **Z > Y > MS**

- **lower metallicity stars**: lower s-process seeds and higher T_{max}
→ **increasing s-process efficiency** with **decreasing metallicity**

Why Such A Wide Range of $^{14}\text{N}/^{15}\text{N}$ Ratios?

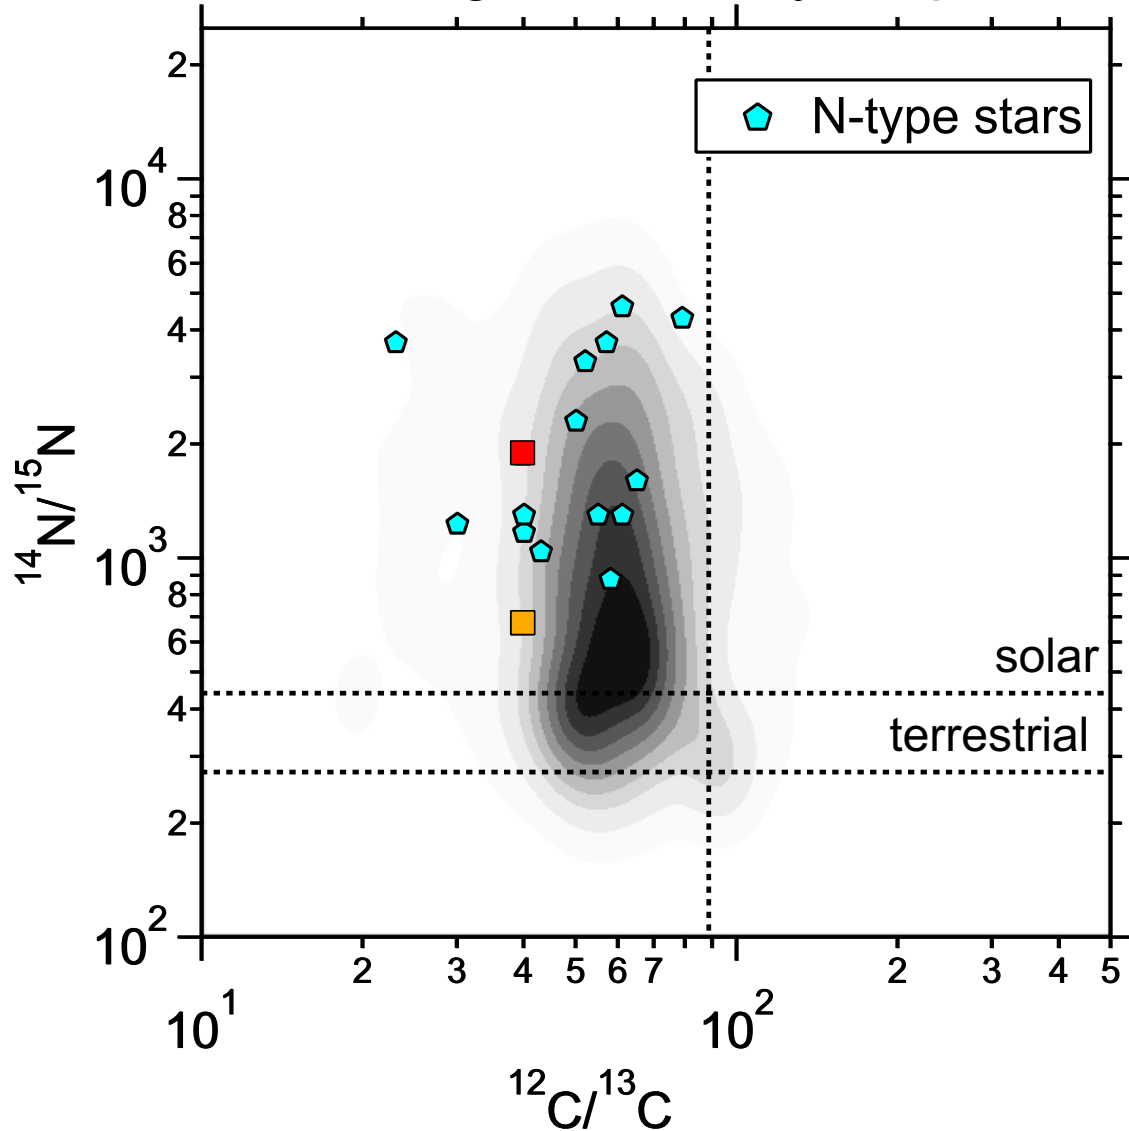

MS/Z and Y: Different $^{12}/^{13}\text{C}$ ratios

MS, Y, and Z : Different Si isotope ratios

MS, Y, and Z: Similar $^{14}\text{N}/^{15}\text{N}$ ratios?

Why Such A Wide Range of $^{14}\text{N}/^{15}\text{N}$ Ratios?

MS grain density map

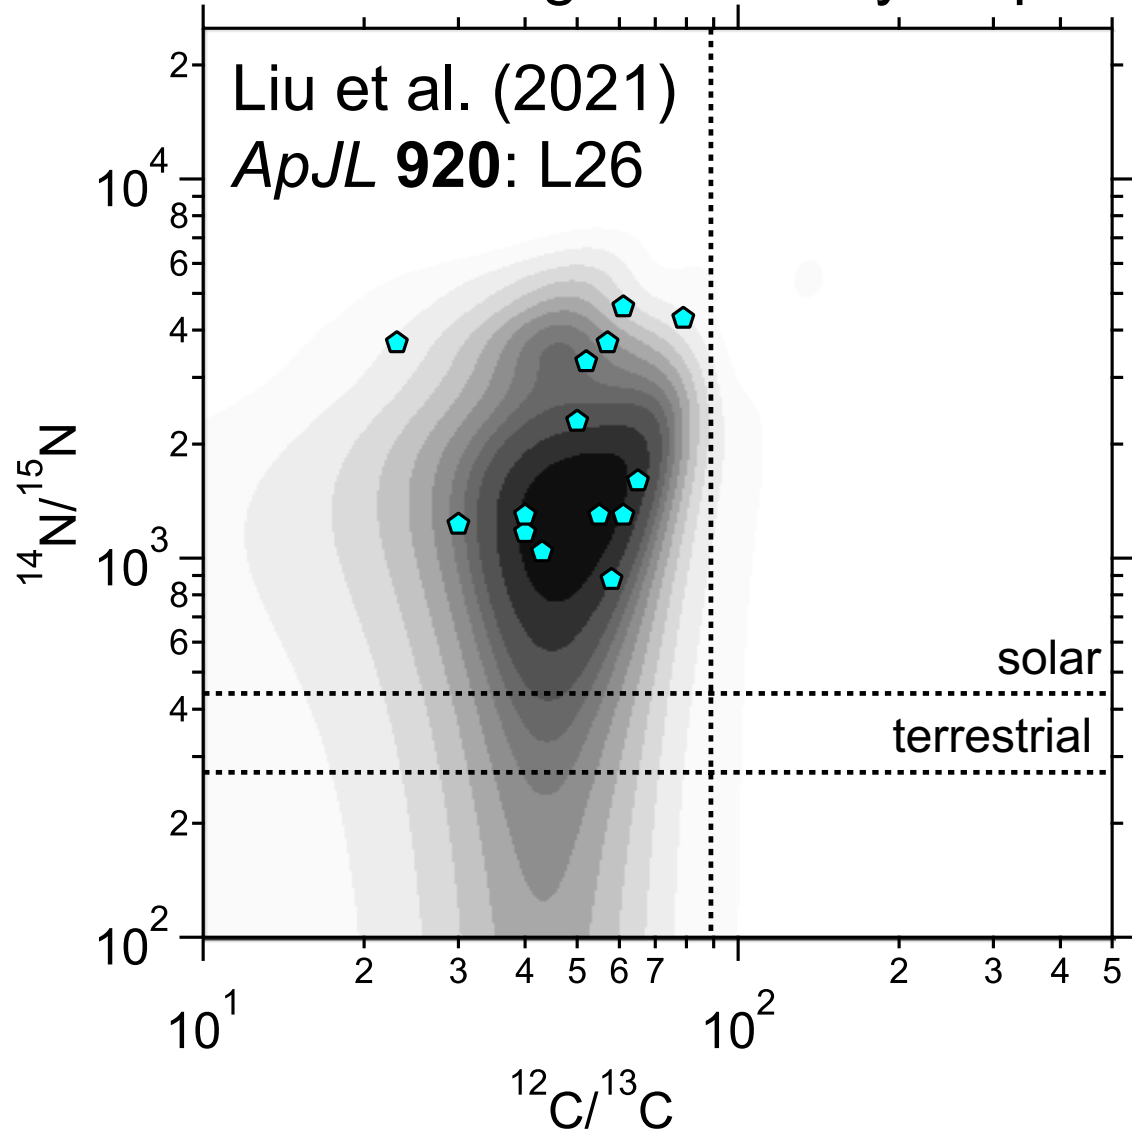

$$^{14}\text{N}/^{15}\text{N} = 676 \pm 13$$

$$^{14}\text{N}/^{15}\text{N} = 1897 \pm 136$$

Isotope data of presolar grains are subject to **contamination** and may **not** reflect **intrinsic stellar signatures!**

Suppressing N Contamination

$^{14}\text{N}/^{15}\text{N}$ Affected by Stellar Mass and Metallicity

- $^{14}\text{N}/^{15}\text{N}$: increases with increasing stellar mass
- $^{12}\text{C}/^{13}\text{C}$: increases with increasing stellar mass and decreasing stellar metallicity

MS, Y, and Z: Different $^{14}\text{N}/^{15}\text{N}$ ratios?

NEW Y and Z grains

- $^{14}\text{N}/^{15}\text{N}$: increases with increasing stellar mass
- $^{12}\text{C}/^{13}\text{C}$: increases with increasing stellar mass and decreasing stellar metallicity

- Higher $^{14}\text{N}/^{15}\text{N}$ in Z grains: higher stellar mass?
- Effects of extra mixing on $^{12}\text{C}/^{13}\text{C}$ and $^{14}\text{N}/^{15}\text{N}$?

$^{26}\text{Al}/^{27}\text{Al}$ in AGB SiC Grains

Liu et al. (2021) *ApJL* **920**: L26

$$(^{26}\text{Al}/^{27}\text{Al})_0 = 8.3 \times 10^{-4}$$

$$(^{26}\text{Al}/^{27}\text{Al})_0 = 1.9 \times 10^{-3}$$

- Al contamination affected literature data for $(^{26}\text{Al}/^{27}\text{Al})_0$
- New data suggest most AGB grains have $(^{26}\text{Al}/^{27}\text{Al})_0$ of $(1-2) \times 10^{-3}$

- Nonmagnetic FRUITY models predict $(^{26}\text{Al}/^{27}\text{Al})_0$ of $(2-4) \times 10^{-3}$ for C-rich phase
- The model results can be reduced by increasing the $^{26}\text{Al}_g(p,\gamma)^{27}\text{Si}$ rate

FRANEC Torino AGB Models

Grains versus Models

Magnetic FRUITY AGB Models
Problem: cannot reproduce the large ^{30}Si excesses in Y and Z grains

FRANECA Torino AGB Models
Problem: Why parent stars of Y and Z grains had such low amounts of ^{13}C ?

Y and Z Grains: SiC from low-metallicity AGB stars?

Liu et al. (2019)
ApJ **881**: 28

Conclusions

- MS, Y and Z grains show systematic **differences** in **C, Si, Ti, Sr, Ba** isotope ratios
 - The large **^{30}Si , ^{50}Ti , ^{88}Sr , and ^{138}Ba enrichments** observed in Y and Z grains are in line with signatures **expected for low metallicity AGB stars**, but AGB models **cannot quantitatively** explain the grain data
-
- MS, Y, and Z grains show **similar N, Mg-Al, and Mo isotope ratios**, and the **similar N and Mg-Al** isotope data may have been caused by **contamination** and need further investigation
 - The **new NanoSIMS analytical approach** is needed to obtain **more N and Mg-Al** isotope data for **Y and Z grains**
 - That the **Mo isotopic pattern varies** with varying metallicity is caused by the **MACS values** of Mo isotopes **deviating from $1/v_{\text{th}}$** , and better cross-section measurements are needed to test whether this is true.
