

Progress on PID electors

Leonid Burmistrov

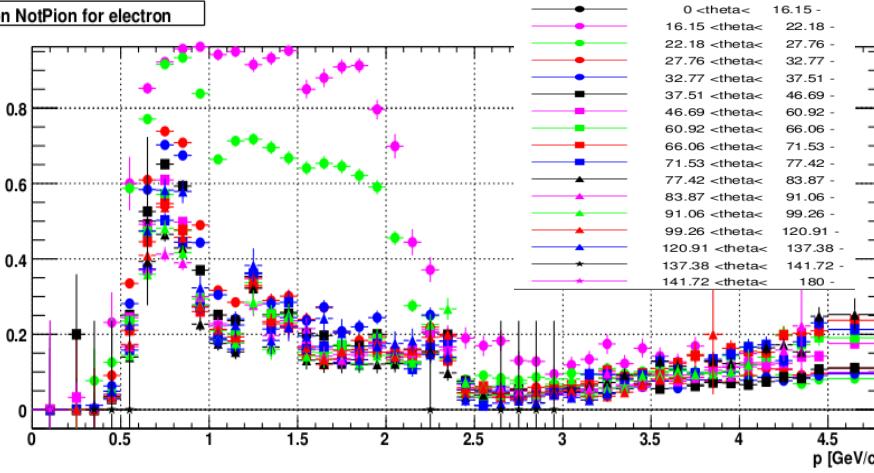

- New table based selectors
 - Motivation
 - Implementation in FastSim
 - Validation
- New Table based electron KM selectors
- New Table based Proton LH selectors
- Anti electron Likelihood selector

Motivation

As you can see efficiency of the PID selectors is a function of theta. In old tables we have just 3 theta regions (good approximation for kaon and pion) – Forward , Barrel , Backward.

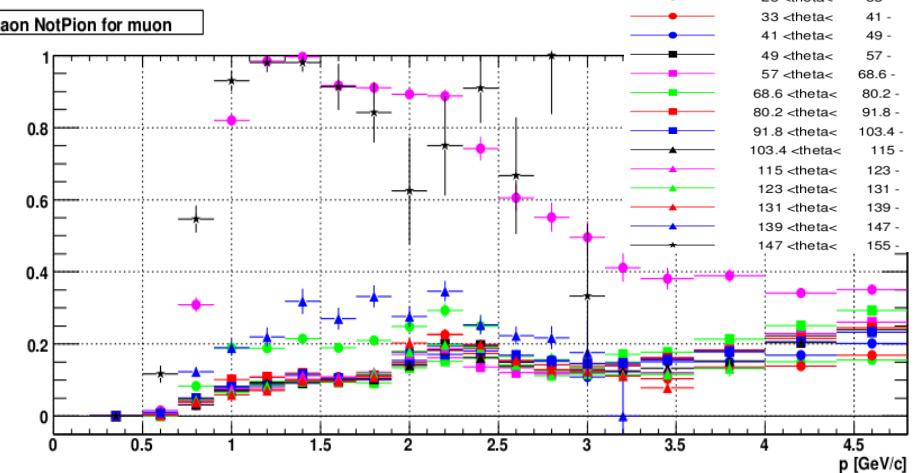

Kaon not a pion for different p, theta (Babar tables)

Kaon NotPion for electron

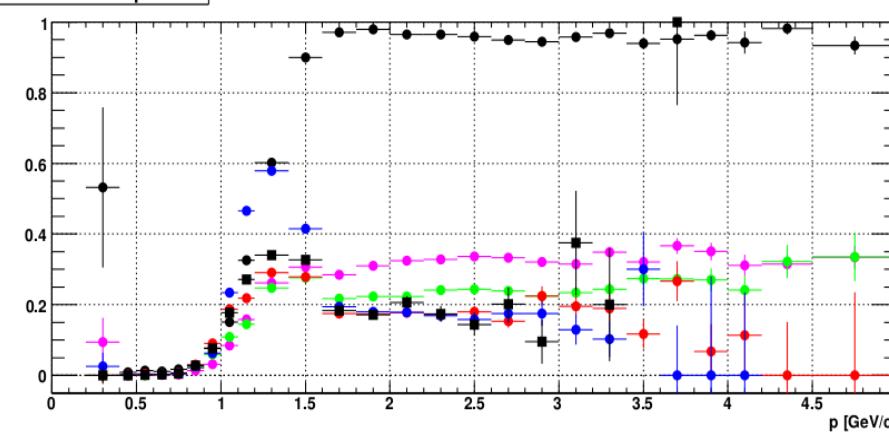

electrons

Kaon NotPion for muon

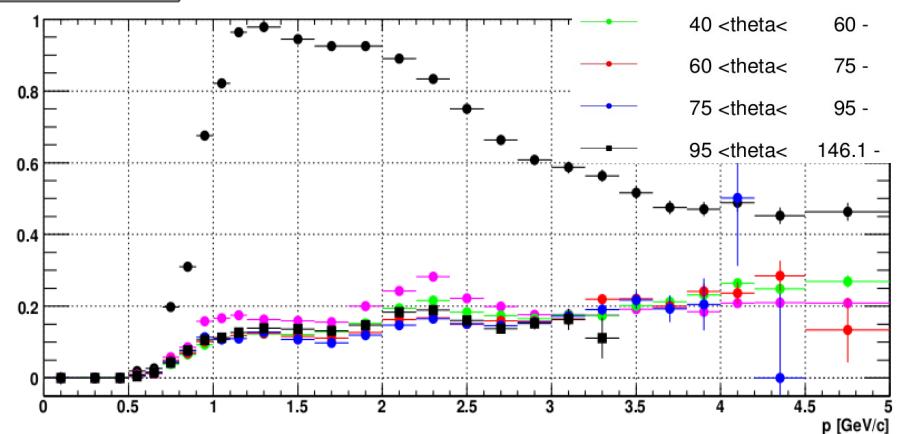

muons

Kaon NotPion for proton

protons

Kaon NotPion for pion

pions

Implementation in FastSim

- Due to different number and size of the theta and momentum bins structure of the new tables is very different from old. So different function need to be used to read them
- New Class **TableReader** was written to read tables

TableReader::ReadNewTable(HepString path) – to read new tables

TableReader::ReadOldTable(HepString path) – to read old tables

TableReader::GetAcceptProb(double p, double theta, PdtPid::PidType partID) – return probability to be accepted

To read new tables **newTableFlag = true** in **PacPid<Particle>Sequence.tcl**

All new tables are here:

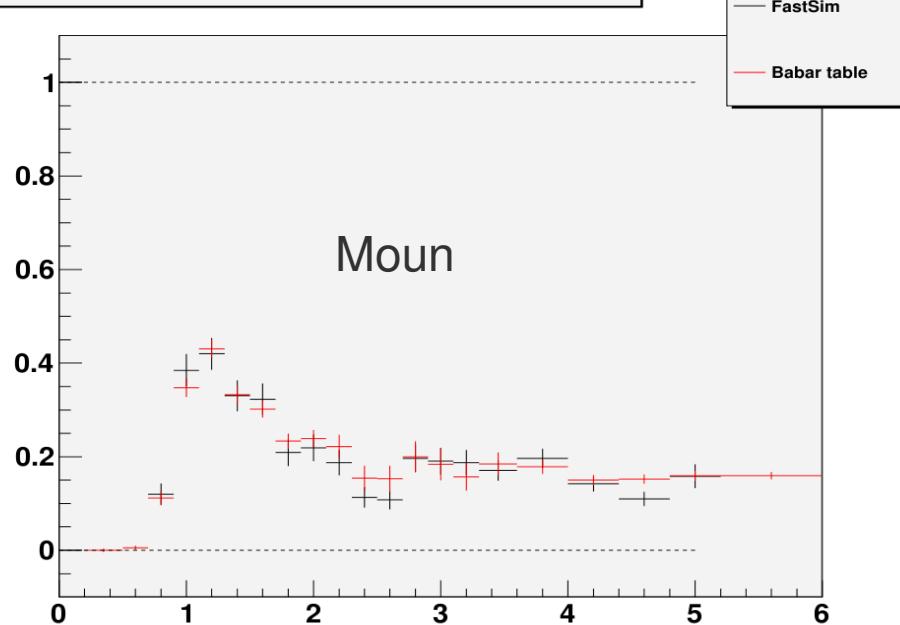

PacPidCalib/PidTables/TablesNew7feb2010/

New Tables

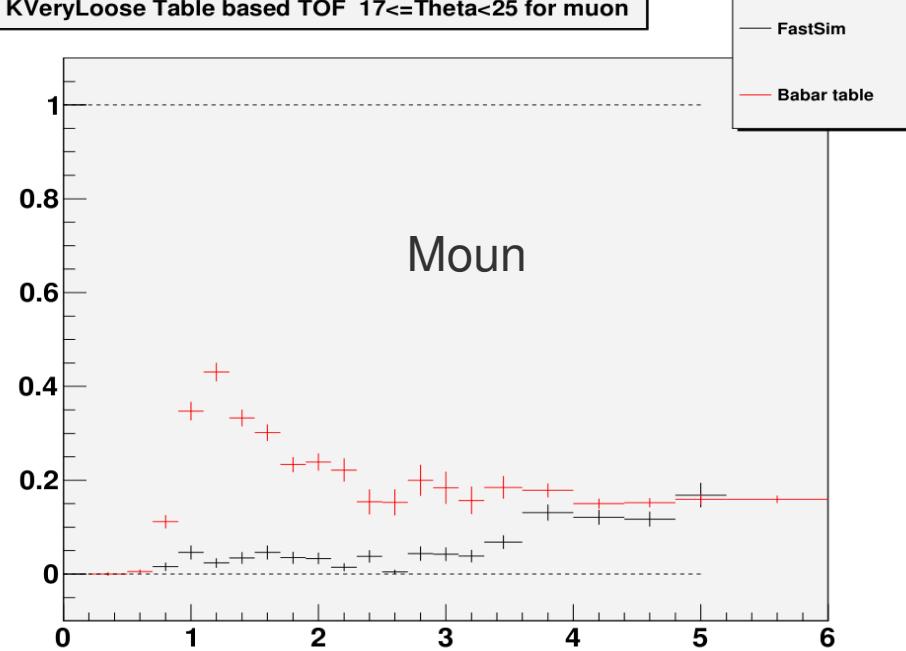

Validation

Old Tables

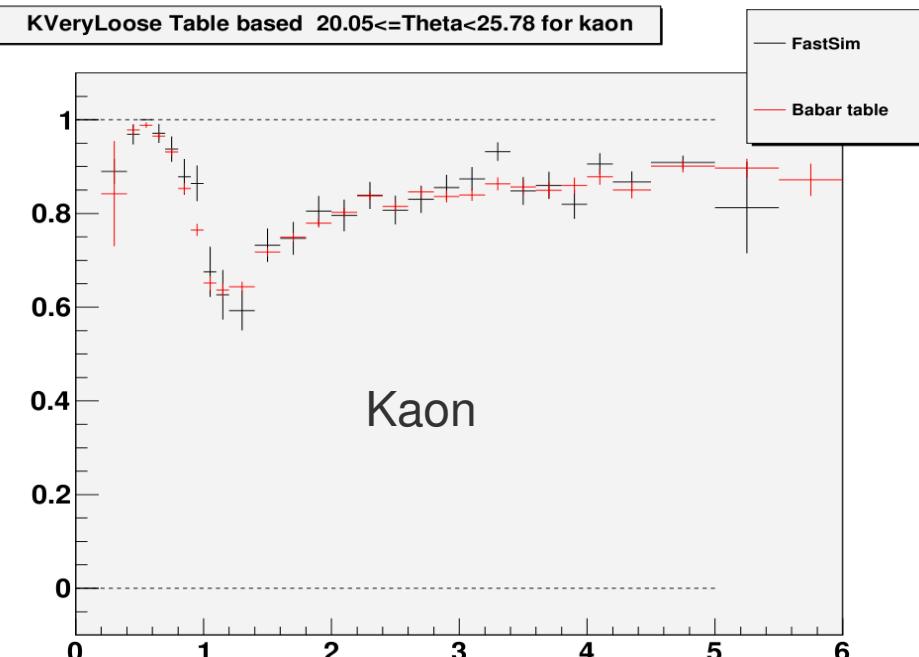

KVeryLoose Table based $17 \leq \text{Theta} < 25$ for muon

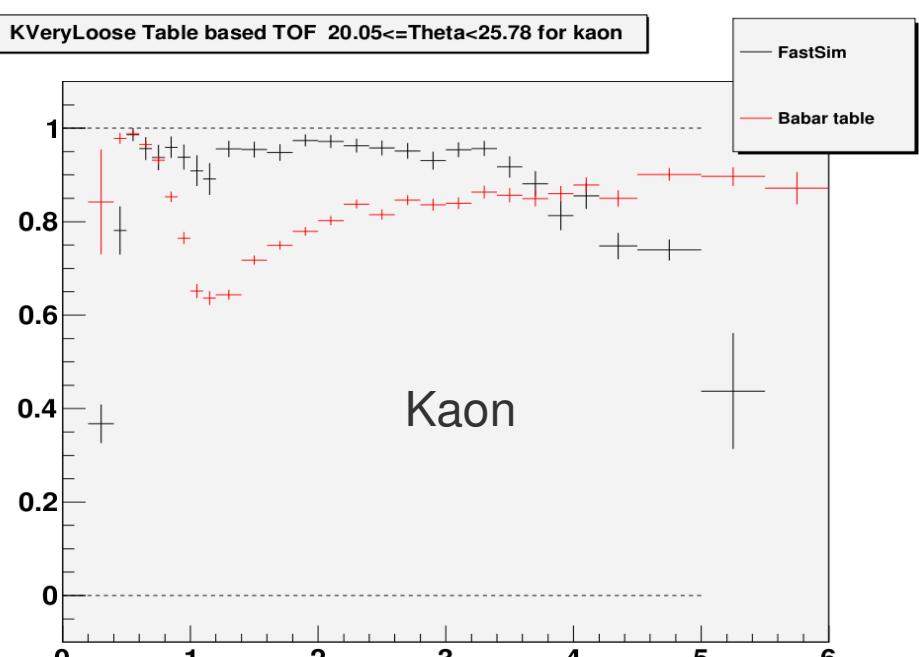

KVeryLoose Table based TOF $17 \leq \text{Theta} < 25$ for muon

KVeryLoose Table based $20.05 \leq \text{Theta} < 25.78$ for kaon

KVeryLoose Table based TOF $20.05 \leq \text{Theta} < 25.78$ for kaon

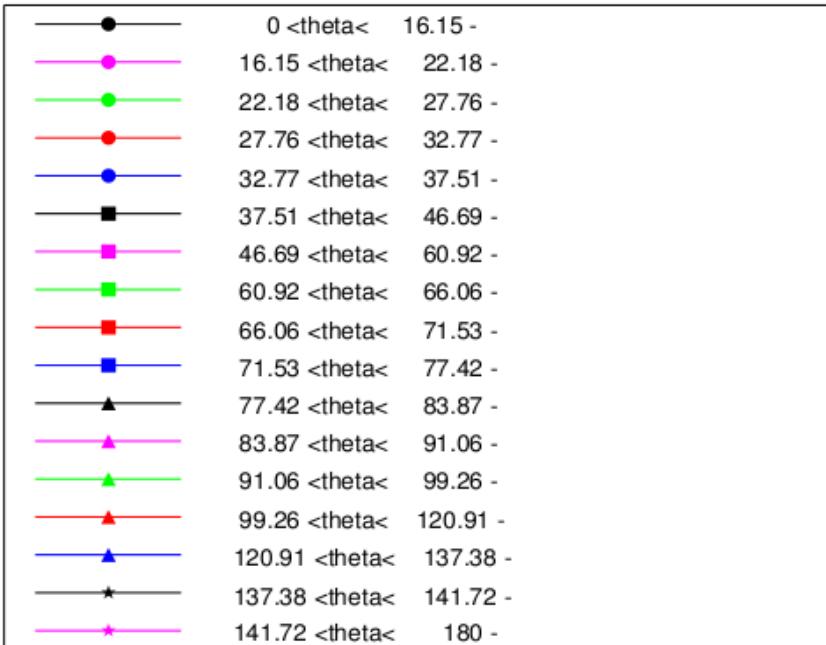

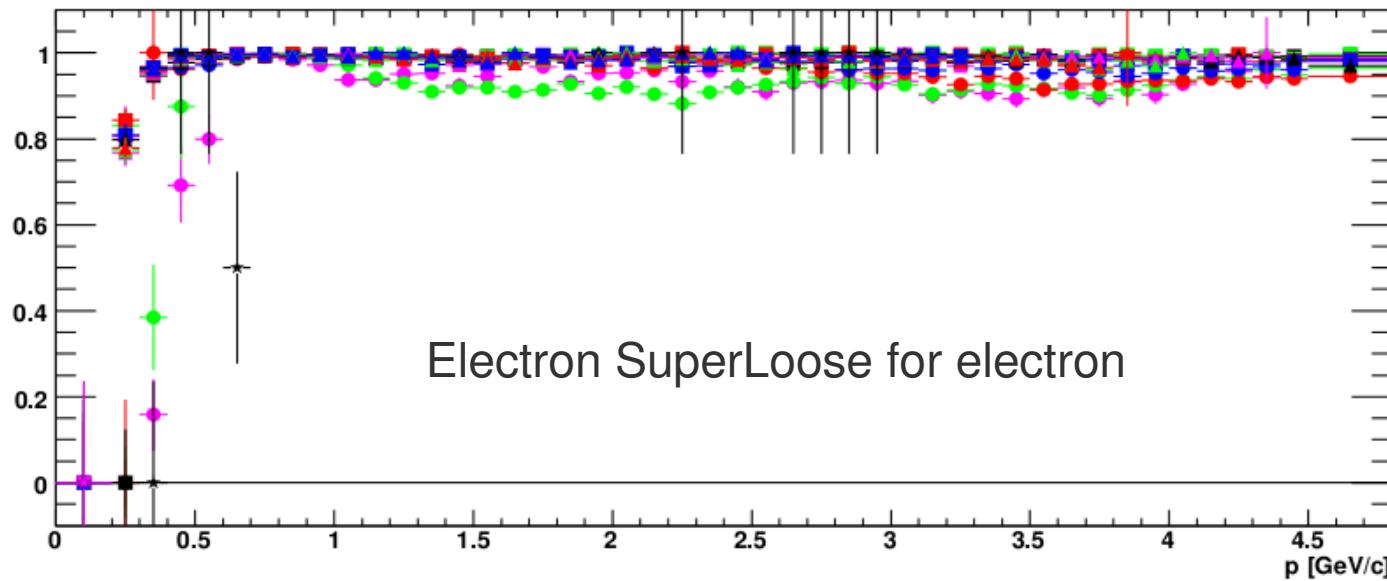

Kaon

Kaon

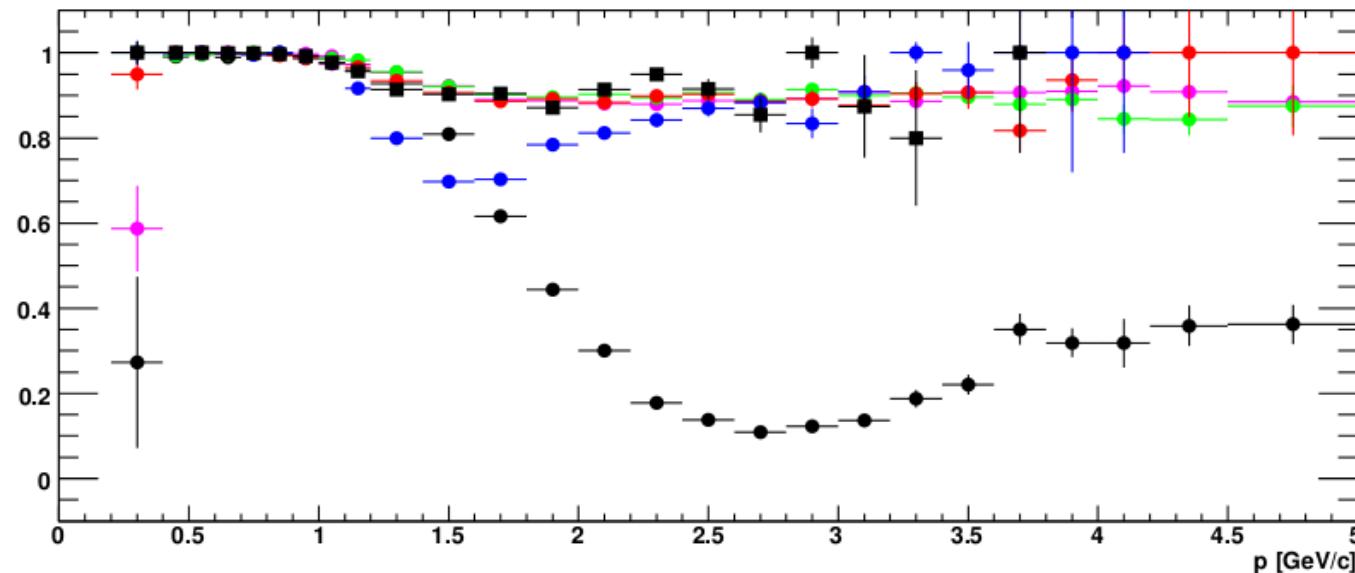

New Table based electron KM selectors

Electron SuperLoose for electron

New Table based Proton LH selectors

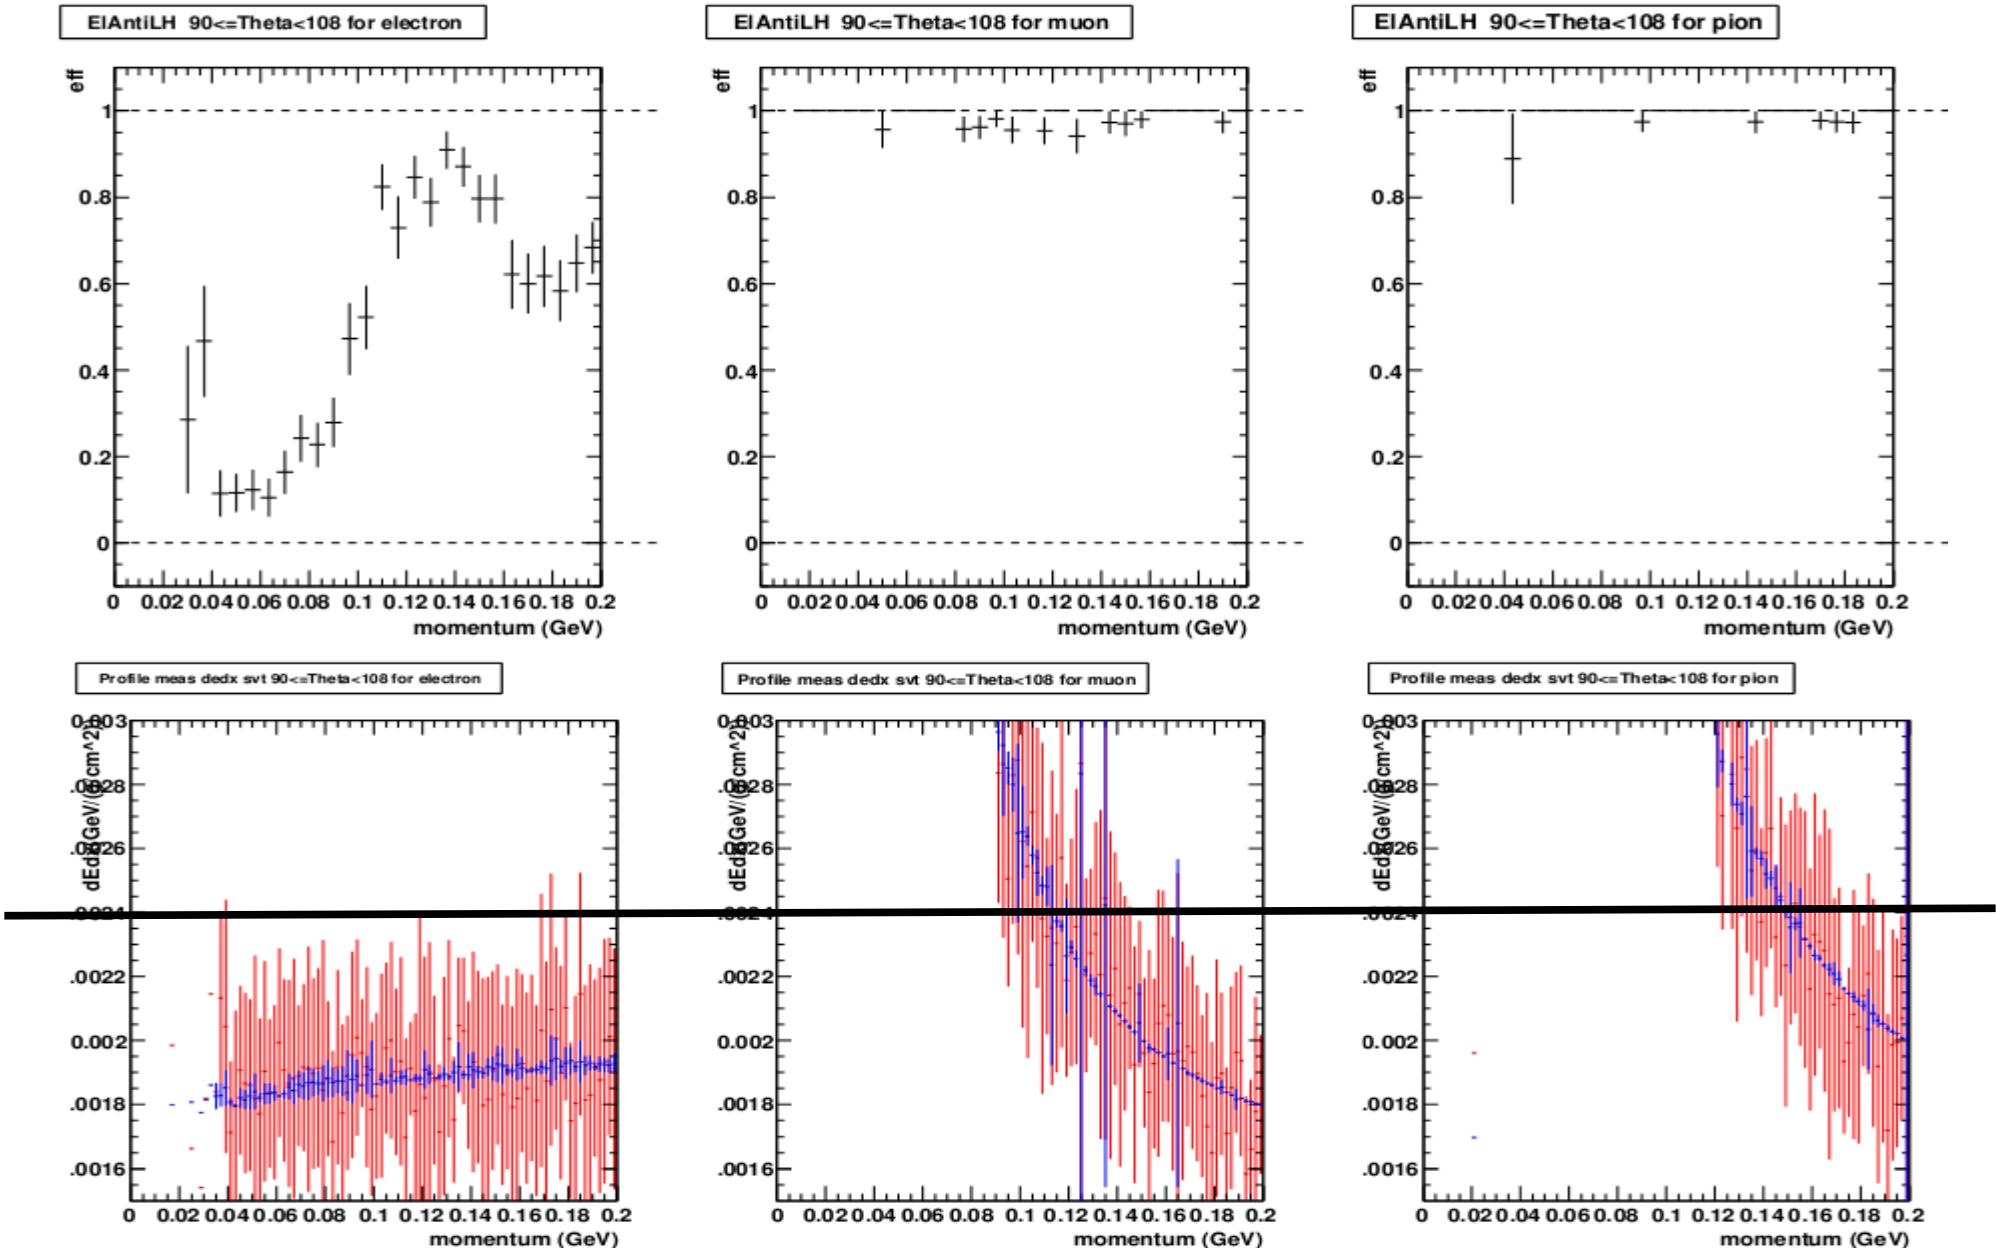

ProtonLH Loose for proton

| | | |
|-----|-----------------|---------|
| —●— | 20.05 < theta < | 25.78 - |
| —●— | 25.78 < theta < | 40 - |
| —●— | 40 < theta < | 60 - |
| —●— | 60 < theta < | 75 - |
| —●— | 75 < theta < | 95 - |
| —■— | 95 < theta < | 146.1 - |

Anti electron Likelihood selector

- We construct this variable: $R_{ELvsAll} = LH_{el}/(LH_{el} + LH_{mu} + LH_{pi} + LH_k + LH_p)$
- We ask $R_{ELvsAll}$ to be < 0.95
- This selector can be improved by constructing several ratios (R_{ElvsMu} and R_{ElvsPi})
 $R_{ElvsMu} = LH_{el}/(LH_{el} + LH_{mu})$ $R_{ElvsPi} = LH_{el}/(LH_{el} + LH_{mu})$

Conclusions

- New Tables where constructed and tested
- We add:
 - 6 new electron KM selectors (table)
 - 4 new proton LH selector (table)
 - 1 anti electron LH selector (real)
- Need to commit the code
