## The Standard Model

#### What is "beyond" the SM (in this talk)?

## Beyond

## The Standard Model

#### SN1987A: the marvel of the last century

Feb 23, 1987

- Took place 168,000 years ago
- In the Large Magellanic Cloud, 50 kpc away.  $18M_{\odot}$  star.

#### "Many" neutrinos were observed

- O(30) events in total.
- One of the first examples of multimessenger astronomy.
- Neutrinos before photons.
- Not enough statistics, still a coherent picture can be formed!

#### A supernova engine

Talk by Burrows, Janka for further details

#### Supernova neutrino luminosity

#### Neutrino propagation inside a SN

#### The governing Hamiltonian

• Easier to study the behaviour of the flavour ensemble, through

 $\varrho = \begin{bmatrix} \langle \nu_e | \nu_e \rangle & \langle \nu_e | \nu_x \rangle \\ \langle \nu_x | \nu_e \rangle & \langle \nu_x | \nu_x \rangle \end{bmatrix}$ 

• The Eq. of motion  $d_t \varrho_p(r, p, t) = -i[H_p, \varrho_p] + C[\varrho_p]$ 

Collective neutrino oscillations

Talk by Kneller for further details

#### What sort of a laboratory is the SN?

Advent of multi-messenger astronomy

- $\nu$ s probe stellar interiors.
- Relevant information about supernova dynamics, shockwave propagation, turbulence.
- Physics of dense neutrino streams. Can lead to "collective oscillations"!

- Non-standard (self)interactions, decay, magnetic moment, millicharge, etc.
- New particles: sterile neutrinos, axions, majorons, etc.
- Any crazy stuff that theorists can think about.

Category of bounds from SN neutrinos

**New Physics can** 

1. Impact on the neutrino luminosity, and average energy, and duration of neutrino burst

2. Impact on the neutrino spectra/ flux

# Impact on the neutrino luminosity, and average energy

## SN cooling bound

- New modes of energy loss due to weakly coupled particles.
- If  $\mathscr{L}_x > \mathscr{L}_\nu \sim 10^{52} \, \mathrm{erg/s}$ , then duration of neutrino burst is reduced.
- $g < g_{\min}$ : not efficiently produced.  $g > g_{\max}$ : efficiently trapped and reabsorbed (trapping mechanism needs to be well understood)

 $L_x \propto g_x^2$ ,

Volume

Blackbody

FIG. 1. Schematic dependence of  $L_x$  on the coupling strength  $g_x$ . The horizontal line denotes the neutrino luminosity  $L_v$ . In the range  $g_{\min} < g < g_{\max}$  the LEP emission  $L_x$  would exceed  $L_v$ .

Raffelt and Seckel, (PRL 1998) Raffelt, Stars as laboratories for fundamental physics, UCP (1996)

• Further improvements in treatment recently.

Caputo, Raffelt, Vitagliano (JCAP 2022)

# 1. The dark photon, and other light friends in SN

## Different dark photon models

- 1. Vanilla Dark photon ~  $\mathscr{L} \supset \frac{1}{4}F'F' + \frac{\epsilon}{2}FF'$
- Consider free-streaming and trapping limit. Main production from  $pp \rightarrow ppA'$ ,  $np \rightarrow npA'$ .

Dent, Ferrer, Krauss, arXiv 1201.2683

- Include finite temperature and density effects in A' production.
   Chang, Essig, McDermott, (JHEP 2017)
- Bounds can be further strengthened by considering decay to e<sup>+</sup>e<sup>-</sup>, γ,
   both in the mantle, and near the progenitor surface.

Kazanas, Mohapatra, Nussinov, et al., (NPB 2015) DeRocco, Graham, Kasen, et al., (JHEP 2019)

## Inclusion of muons from simulations

- For lower Z' masses, semi-Compton process relevant.
- Upper bound fixed by trapping arguments.
- 3. Axion-muon coupling gauge boson.
- Probe of axion physics

 $\mu\gamma \rightarrow \mu a$ 

 $\mu p \rightarrow \mu p a$ 

Croon, Ellor, Leane, McDermott, (JHEP 2021)

# 2. Sterile neutrinos in SN

## Sterile neutrinos in supernova

- Sterile neutrino production in SN, through
   (i) adiabatic MSW conversion at radii
  - 10-15 km inside neutrinosphere.

(ii) collisional production due to  $\nu_{\mu,\tau} - n$  scattering.

 Interplay of two main parameters: width of the resonance region and the oscillation length, and m.f.p.

Arguelles, Brdar, Kopp, (PRD 2019)

## But..feedback is important

- $\nu_s$  is produced from  $\nu_a$ . This affects the  $V_{\rm eff}$ , which again affects flavor conversions: feedback.
- Neglecting feedback drastically over-estimates the  $\nu_a$  lepton number.
- Including feedback in multi-zone models relaxes SN bounds.

Tamborra, Wu, Suliga, (JCAP 2019)

See also Raffelt and Zhou (PRD 2011), for an earlier discussion of feedback in one-zone models.

## $\nu_{s}$ DM from neutrino self-interactions

•  $\nu_s$  can also be produced inside the SN core due to new interactions  $\mathscr{L} \supset \lambda_{aa} \nu_a \nu_a \phi$ Lead to additional cooling channels. Strong bounds!

• Bound :  $L \leq 3 \times 10^{52} \, \text{erg/s.}$ 

Chen, **MS**, Tuckler, et al. (JCAP 2022)

# Impact on the neutrino spectra/flux

#### The neutronization burst: a foreward

- Large burst of  $\nu_e$  in the first ~30 ms post bounce.
- Robust feature of all simulations.
- Large  $\nu_e$  excess, hence no collective oscillations within the SM. (Remember  $\nu_e \overline{\nu}_e \leftrightarrow \nu_\mu \overline{\nu}_\mu$ !)

#### Sensitivity to neutrino mass ordering

 $\nu_e$  is produced as  $\nu_3$  ( $\nu_2$ ) in NH (IH).

$$\begin{split} L_{\nu_e}(R_E) &\simeq |U_{e2}|^2 L_{\nu_e}^0 = 0.2 L_{\nu_e}^0 & \text{IH} \\ L_{\nu_e}(R_E) &\simeq |U_{e3}|^2 L_{\nu_e}^0 = 0.03 L_{\nu_e}^0 & \text{NH} \end{split}$$

Independent probe of mass ordering!

Dighe, Smirnov (PRD 2000)

#### Sensitivity to neutrino mass ordering

3. Non-standard (self)interactions

## Non-standard interactions

• Presence of NSI can lead to important consequences in dense core  $\mathscr{L} \supset \varepsilon_{\alpha\beta}^{fP} 2\sqrt{2}G_F (\bar{\nu}^{\alpha} \gamma^{\mu}L \nu^{\beta}) (\bar{f}\gamma_{\mu}Pf)$ 

• Extra potential 
$$V = \sqrt{2}G_F N_f \varepsilon_{\alpha\beta}^{fP}$$

- Leads to an extra resonance ('I' resonance) if  $H_{ee} = H_{\mu\mu}, H_{\tau\tau}$ . Changes flavor content deep inside the SN.
- Can reduce  $Y_e$  during collapse, leading to lower shock energy.

Amanik, Fuller, (PRD 2007) See also Amanik, Fuller, Grinstein, Astropart. Phys (2005)

Esteban-Pretel, Tomas, Valle, (PRD 2007)

## A neutrinophilic $\phi$

- Consider a neutrinophilic scalar  $\mathscr{L} \supset g \nu \nu \phi$
- Leads to vv → 2v2v. Doubles v
   number density, but energy is halved.
   Cannot transfer enough energy
   to stalled shock (red region).
- Additional bounds from scattering with  $C\nu B$ , and losing energy (blue region).
- Additional bounds due to modification of stellar physics.

Fuller, Mayle, Wilson, Astrophys. J. (1988) Kachelreiss, Tomas, Valle, (PRD 2000) Farzan (PRD 2000)

Shalgar, Tamborra, Bustamante, (PRD 2020)

## Non-standard self-interactions

• Consider  $\mathscr{L} \supset G_F (G_{\alpha\beta} \bar{\nu}^{\alpha} \gamma^{\mu} L \nu^{\beta}) (G_{\eta\delta} \bar{\nu}^{\eta} \gamma^{\mu} L \nu^{\delta}),$ 

$$x = \mu, \tau$$

where most generally, 
$$G = \begin{pmatrix} 1 + g_{ee} & g_{ex} \\ g_{ex} & 1 + g_{xx} \end{pmatrix}$$

• Non-linear EoMs, extremely sensitive to 
$$\nu$$
SI.  
 $i d_t \varrho_p = \left[ H_{\text{vac}} + H_{\text{mat}} + \sqrt{2}G_F \int d\mathbf{q} \, \boldsymbol{G} \, \varrho_q \, \boldsymbol{G} \,, \varrho_p \right],$ 
Raffelt, Sigl (Non-linear EoMs, extremely sensitive to  $\nu$ SI.

Raffelt, Sigl (NPB 1993) Blennow, Mirizzi, Serpico (PRD 2008)

 g<sub>ex</sub> ≠ 0 can populate ν<sub>x</sub> from ν<sub>e</sub> during neutronization. Cause collective oscillations now, giving distinct spectral splits in neutronization spectra.

Das, Dighe, MS (JCAP 2017)

# 4. Neutrino decay & properties

## Non-standard neutrino decay

- Massive neutrinos can decay to lighter ones even within the SM. Age longer than universe.
- New physics can mediate faster decay.

 $\mathcal{L} \supset \nu_h \nu_l \phi + \mathrm{H.c.}$ 

$$u_{hL} \rightarrow \nu_{lL} + \phi \quad \dots$$
 Helicity cons. (h.c.)  
 $u_{hL} \rightarrow \nu_{lR} + \phi \quad \dots$  Helicity flip. (h.f.)

Use the neutronization flux to (i) Put some of the tightest bound on this decay. (ii) Distinguish between Dirac and Majorana nature.

## The game plan

Normal Ordering

Ando PRD (2004) de Gouvea, Martinez-Soler, **MS** (PRD 2019)

For a detailed theoretical framework of neutrino decay, see Lindner, Ohlsson, Winter, (NPB 2002)

#### Enhancement in spectra

#### Simulated data in DUNE

de Gouvea, Martinez-Soler, MS (PRD 2019)

### Simulated data in DUNE

## Dirac vs Majorana

acts as an "inert" neutrino and cannot be observed.

$$\mathcal{L}_{\mathrm{Maj}} \supset \nu_h \nu_l \phi + \mathrm{H.c.}$$

$$\nu_{hL} \rightarrow \nu_{lL} + \phi$$

$$\nu_{hL} \rightarrow \nu_{lR} + \phi$$
if

acts as the "antineutrino" - produces an  $e^+$  on interaction—observable

Different signatures in detectors sensitive to  $\nu_e$  and  $\overline{\nu}_e$ .

#### Look at DUNE and HK

#### Distinguishing capacity: Dirac(D) vs Majorana (M)

- Simulate data consistent with Dirac neutrinos and  $\tau/m = 10^5$ s/eV.
- A combination of DUNE+ HK can distinguish between Dirac and Majorana neutrinos at  $5\sigma$ .

de Gouvea, Martinez-Soler, **MS** (PRD 2019)

### Pseudo-Dirac neutrinos

Martinez-Soler, Perez-Gonzalez, MS (PRD 2022)

Esmaili, Farzan, (JCAP 2012)

#### Pseudo-Dirac neutrinos: SN1987A

Rules out  $\delta m^2 \sim [2.5, 3.] \times 10^{-20} \text{eV}^2$  by more than  $3\sigma$ .

Slight preference for  $\delta m^2 = 6.31 \times 10^{-20} \text{eV}^2$  over the un-oscillated scenario by  $\Delta \chi^2 \approx 3$ .

#### Neutrinos from all supernovae

#### Other new physics-an incomplete list

• Axions, and axion-like particles.

Raffelt, Stars as laboratories for fundamental physics, UCP (1996) Jaeckel, Spannowsky, (PLB 2016) Lucente, Carenza, Fischer, et al. (JCAP 2020)

Majorons and other feebly interacting scalars.

Kachelreiss, Tomas, Valle, (PRD 2000) Farzan (PRD 2000) Fiorillo, Raffelt, Vitagliano, 2209.11773

• Neutrino magnetic moment: bounds  $\mu_D < 10^{-12} \mu_B$ .

Barbieri, Mohapata, (PRL 1988) Jana, **MS**, Silva (JCAP 2022)

- Radiative decays:  $\nu \rightarrow \nu' \gamma$ , gives a coincident  $\gamma$ -ray flare. Bounds Raffelt, Stars as laboratories for fundamental physics, UCP (1996)  $\tau/m > 10^{15}$  s/eV.
- Time of flight delay due to neutrinos:  $m_{\nu} < 20 \,\mathrm{eV}$ . Zatsepin, JETP Lett (1968) More precise time measurements narrow it to O(1)eV.

Talk by Pompa for further details

Hansen, Lindner, Scholer, (PRD 2020) Pompa, Capozzi, et al (PRL 2022)

• If  $\nu$  have millicharge, their path can be bent by galactic B field, causing a time delay,  $e_{\nu} < 10^{-17} e (1 \mu G/B)$  Barbiellini, Cocconi, Nature (1987)

## Conclusion

- A core-collapse SN is one of the best astrophysical laboratories for fundamental neutrino physics.
- Can use neutrino luminosity constraints to put bounds on exotic new particles.
- Better understanding of the underlying neutrino physics can be leveraged to use the signal to put some of the best bounds on nonstandard neutrino properties, as well as the nature of neutrinos.
- Till a galactic SN takes place, one can utilize the constant availability of the DSNB to already probe some of these physics.

# Backup

## Estimating the DSNB

Cosmology 
$$H(z) = H_0 \sqrt{\Omega_m (1+z)^3 + \Omega_\Lambda (1+z)^{3(1+w)} + (1-\Omega_m - \Omega_\Lambda)(1+z)^2}$$

Manibrata Sen

#### Earth-matter effects

Fig. 39. – Observable signal  $E^2 F_{\bar{\nu}_e}$  with (continuous curve) and without (dotted curve) Earth crossing.

## SN density profile

## Axion bounds

Too many events due to absorption on O, and subsequent  $\gamma$  emission.
