

# Results from TB 2020-07 HOTNES (planar cathode + mesh)

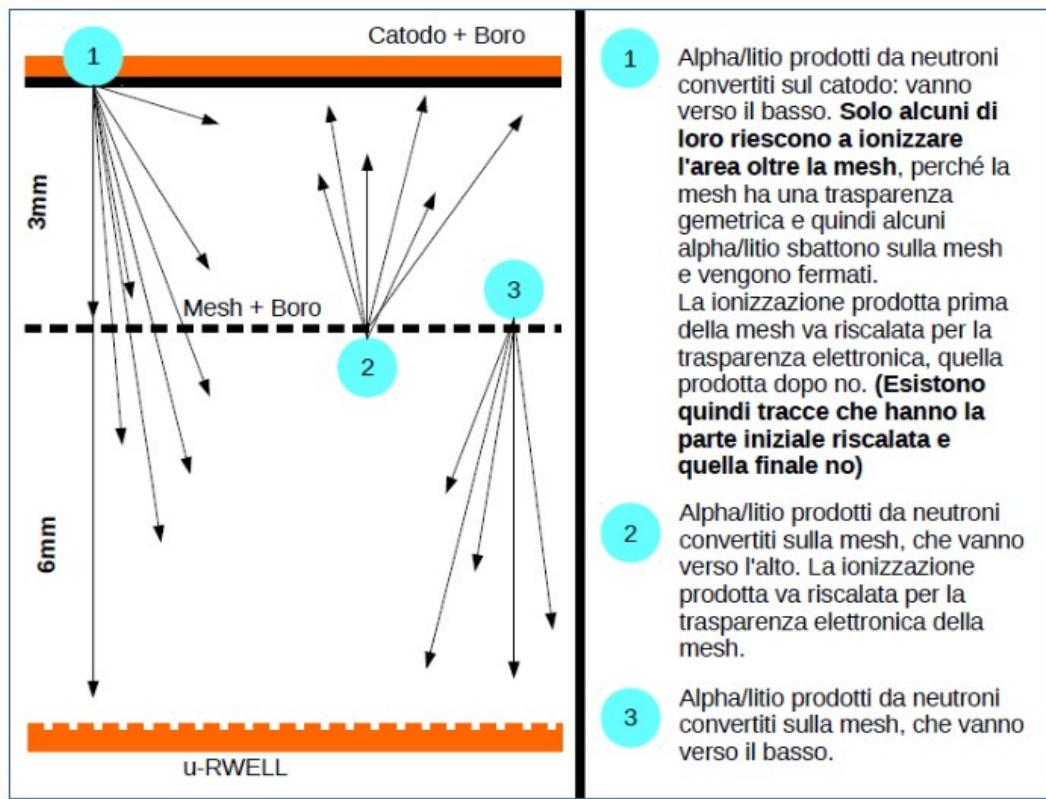

21/05/2021 – uRANIA  
Matteo

# Current calculation

Without the mesh:

$$i = \Phi * \varepsilon * N_{ION} * G * S$$

- $i$  = current ( $C s^{-1}$ )
- $\Phi$  = neutron flux ( $758 cm^{-2} s^{-1}$ )
- $\varepsilon$  = efficiency =  $\# \alpha$  seen/ $\#$ neutrons  $\rightarrow$  from simulation
- $N_{ION}$  = # ele from ionization = primaries & secondaries =  $E_{DEP}/E_{ION}$
- $G$  = gain
- $S$  = surface  $10 \times 10 cm^2$

[by Matteo]

With mesh, there are four contributions:

1-  $\alpha$  from cathode not crossing the mesh  
 $i_1 = \Phi * \varepsilon_1 * N_{ION,1} * G * S * T_{ELE}$

2-  $\alpha$  from cathode crossing the mesh  
 $i_2 = \Phi * \varepsilon_2 * N_{ION,2} * G * S$

3-  $\alpha$  from mesh forward  
 $i_3 = \Phi * \varepsilon_3 * N_{ION,3} * G * S$

4-  $\alpha$  from mesh backward  
 $i_4 = \Phi * \varepsilon_4 * N_{ION,4} * G * S * T_{ELE}$

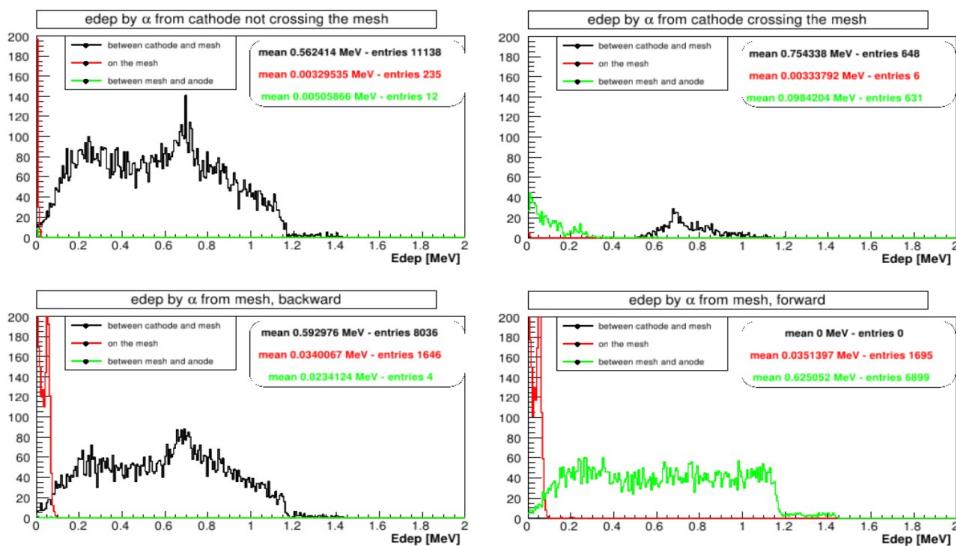

The same must be done with Li ions
