Motivations; Instrument choice and settings

Target: Investigate the noise wavefield at f > 1 Hz.

ET - Site Studies and Characterization Workshop. Nuoro, 8-11 November 2021

Problem 1: at those frequencies, observed noise is below the noise floor of SP seismometers.

Solution [1]: adopt low-noise BB seismometers

Solution 2 \rightarrow High-Gain ADC

However: Issues with dynamics, due to long-period oscillations related to thermal instabilities.

SPatial AutoCorrelation - 1

Under the hypothesis that the noise wavefield is **stochastic** and **stationary in time and space**, the relationship between azimuthally-averaged spatial autocorrelation and phase velocity is (Aki, 1957):

$$\bar{\rho}(r,\omega_0) = J_0 \left[\frac{\omega_0}{c(\omega_0)} r \right]$$

SPAC is calculated at all the independent station pairs over the DC-25Hz frequency band. The dispersion relationship of Rayleigh waves c(f) can then be derived in a variety of manners (non-linear fit by assuming a dispersion functional, from the 0-xings, linearized inversions, etc etc).

SPatial AutoCorrelation - 2

Dispersion curves for individual CCs.

Red lines are the Bessel fits assuming dispersion follows a power law in the form:

 $C(f)=A f^{-b}$

SPatial AutoCorrelation - 3

Here c(f) is derived by the first 0-xing of the correlation curves, with and without averaging $\rho(f,r)$ over consecutive r +/-dr intervals.

The ρ (f,r) function.

Polarization analysis (from eigenstructure of 3C covariance matrix, for subsequent narrow frequency intervals)

Frequency-Slowness Analysis

Deterministic approach: assume the wavefield is composed by plane waves propagating with given azimuth and apparent velocity. **Array Response Functions** serve to evaluate possible aliasing effects due to spatial downsampling

FK-Analysis (Capon's High-Res)

@ f = 4.5 Hz, Propagation azimuths directed WSW (i.e., main sources located ENE of the array). High velocities (> 2.5 km/s).

Largest-amplitude arrivals exhibit timevarying DOA, suggestive of a moving source.

Vehicle Tracking

Time evolution of azimuth compatible with a vehicle traveling at 60 km/h southward along SP73.

Largest signal amplitude is NOT associated when the vehicle is closest to the array, but when it traverses bridge B2

The Autumn Experiments: corners P2 and P3

Experiment @ P2 [18 Sept. 2021 - 27 Sept. 2021]

The plan: 21 stations, 2 circles with radius 75 and 150m

Conclusions

Sos Enattos (P1):

- Anthropogenic contributions peak in between 10 Hz and 20 Hz;
- Narrow spectral peaks @ ~ 4-5 Hz
- Prominent direction of propagation WSW
- SPAC and FK analysis yield consistent results: velocities in the 1500-2500 m/s range over the 5-15 Hz frequency band
- time evolution of directional properties compatible with vehicle traffic along SP73;
- main source of energy at f~ 4.5 Hz likely associated with oscillation of 2 bridges
- Polarization is markedly site-dependent → topographic effects ? Need to sample the seismic wavefield over distances shorter than the characteristic wavelength of morphological irregularities;

The very next steps

- Extend SPAC and FK analyses to horizontal components
- Extend to the whole recording period and other arrays
- Extend to other frequency bands
- Harmonize w/ extended temporal analyses

Pending Questions

- Are noise-based methods well suited for subsurface imaging ?

Thank you for listening
