# AI/ML Tools for analysis of hadron spectroscopy data

13th International Workshop on the Physics of Excited Nucleons Santa Margherita Ligure, Oct 17-21, 2022

Lukasz Bibrzycki
Pedagogical University of Krakow
on behalf of the JPAC collaboration

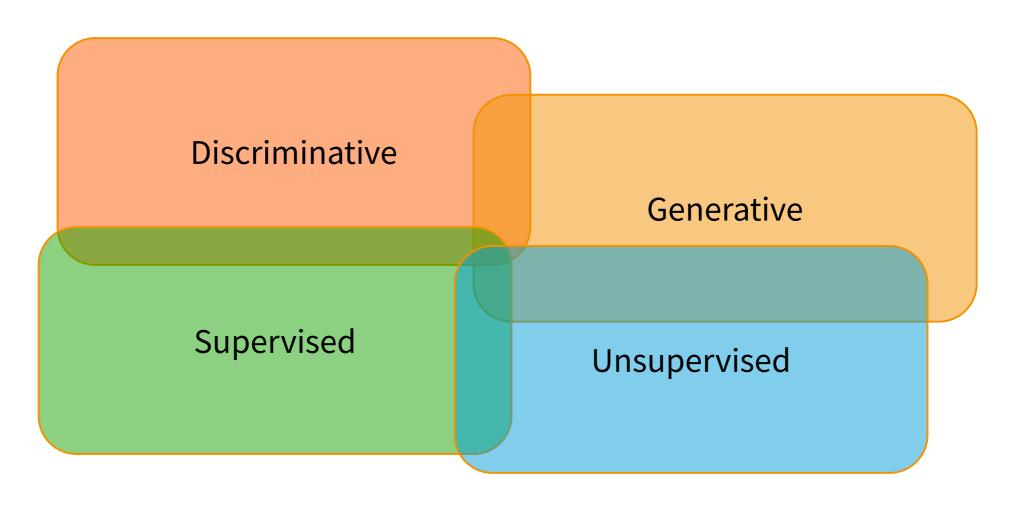

#### Outline

- Motivation and Physical model
- ML model
- Feature refinement
- Model predictions and explanation
- Going beyond discriminative model
- Summary

## Types of ML models

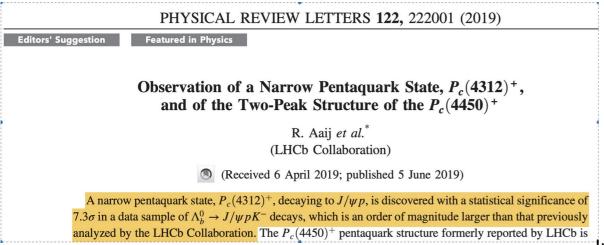

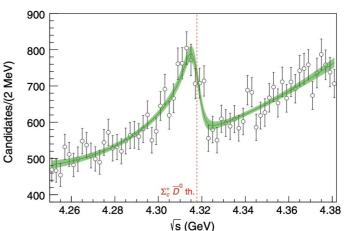

#### Motivation

Plethora of potentially multiquark states observed in last decade

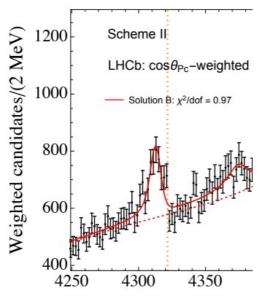

Possible interpretation as duucc pentaquark

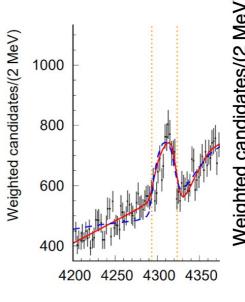

Intensity in the P<sub>c</sub>(4312) neighbourhood and the JPAC fit *C. Fernandez-Ramirez Phys.Rev.Lett.* 123 (2019) 9, 092001

- There is a close relation between QCD spectrum and the analytic structure of amplitudes (production thresholds → branch points, resonances/bound states → poles)
- Currently this relationship is impossible to derive from first principles of QCD (top down approach)
- One can utilize the general properties of amplitudes, like unitarity, analyticity or crossing symmetry, but then model parameters must be derived from data bottom up approach

# Discrepant interpretations of the P<sub>c</sub>(4312) nature

900 800 700 600 400 4.26 4.28 4.30 4.32 4.34 4.36 4.38 Vs (GeV)

Meighted candidates/(2 MeV)  $r_0 = 500 \text{ MeV}$   $r_0 = 500 \text{ MeV$

#### We want to use ANN to:

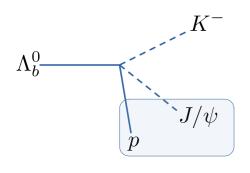

- Go beyond the standard  $\chi^2$  fitting
- Specific questions:
  - Can we train a neural network to analyze a line shape and get as a result the probability of each possible dynamical explanation?
  - If possible, what other information can we gain by using machine learning techniques?
- First attempts to use Deep neural networks as model classifiers for hadron spectroscopy:

Sombillo et al., 2003.10770, 2104.141782, 2105.04898

## Physics model

- P<sub>c</sub>(4312) seen as a maximum in the pJ/ψ energy spectrum
- P<sub>c</sub>(4312) has a well defined spin and appears in single partial wave • Background contributes to all other waves  $\overline{D}^0$  channel opens at 4.318 GeV -coupled

  - $\Sigma_c^+ \overline{D}^0$  channel opens at 4.318 GeV -coupled channel problem

Intensity

$$\frac{dN}{d\sqrt{s}} = \rho(s) \left[ |P_1(s)T_{11}(s)|^2 + B(s) \right]$$

where

$$\rho(s)=pqm_{\Lambda_b} \qquad \text{phase space} \\ p=\lambda^{\frac{1}{2}}(s,m_{\Lambda_b}^2,m_K^2)/2m_{\Lambda_b}, \ q=\lambda^{\frac{1}{2}}(s,m_p^2,m_\psi^2)/2\sqrt{s}$$

$$P_1(s) = p_0 + p_1 s$$
 production term

$$B(s) = b_0 + b_1 s$$
 background term

#### Physics model

Coupled channel amplitudes

$$T_{ij}^{-1} = M_{ij} - ik_i \delta_{ij}$$
 where  $k_i = \sqrt{s - s_i}$   
 $s_1 = (m_p + m_{J/\psi})^2$  and  $s_2 = (m_{\Sigma_c^+} + m_{\bar{D}^0})^2$ 

• Unitarity implies that  $M_{ij}$  is free from singularities near thresholds  $s_1$  and  $s_2$  so that it can be Taylor expanded *Frazer*, *Hendry Phys. Rev.* 134 (1964)

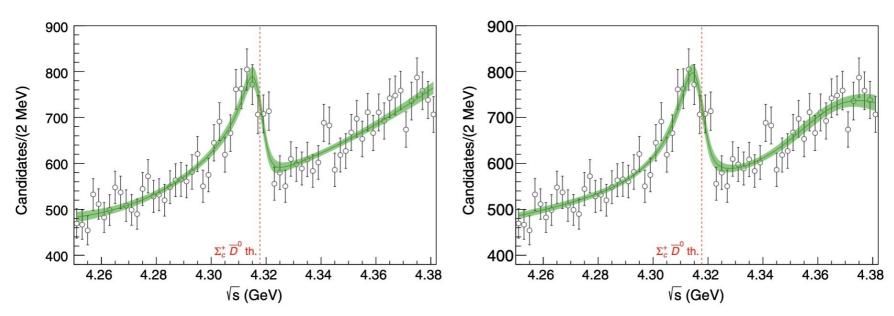

$$M_{ij}(s) = m_{ij} - c_{ij}s$$

• In principle the off-diagonal term of the amplitude  $P_2(s)T_{21}$  could be included but we are interested in the analytical structure ("denominator") – so it's effect can be absorbed to the background and production terms.

#### Physics model – final version

Scattering length approximation

Effective range approximation

See C. Fernandez-Ramirez Phys.Rev.Lett. 123 (2019) 9, 092001

Finally we use the scattering length approximated amplitude as the basis for ML model

$$T_{11} = \frac{m_{22} - ik_2}{(m_{11} - ik_1)(m_{22} - ik_2) - m_{12}^2}$$

THE TOTAL STATE OF THE PEDAGO CICARY

7 model parameters in total:  $m_{11}$ ,  $m_{22}$ ,  $m_{12}$ ,  $p_0$ ,  $p_1$ ,  $b_0$ ,  $b_1$ .

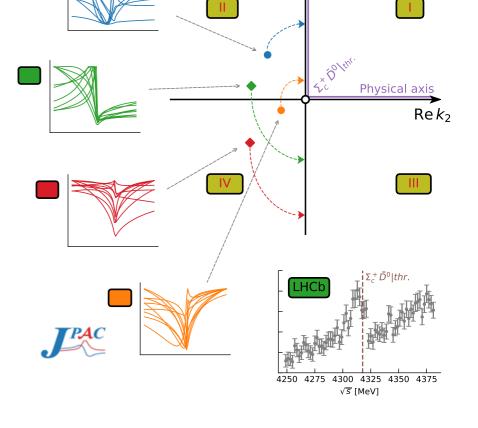

#### ML model – general idea

- From the physical model we produce:
  - Sample intensities (computed in 65 energy bins) produced with randomly chosen parameter samples examples
  - For each parameter sample we are able to compute the target class – one of the four: b|2, b|4, v|2, v|4
  - Symbolically:

 $K: \{[I_1, ..., I_{65}](m_{11}, m_{22}, m_{12}, p_0, p_1, b_0, b_1)\} \rightarrow \{b|2, b|4, v|2, v|4\}$ 

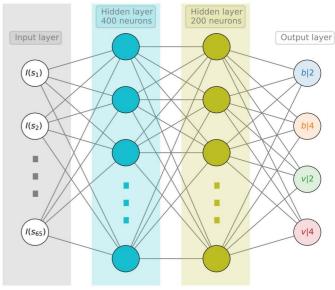

#### ML model – MLP

Layer	Shape in	Shape out
Input		(B, 65)
Dense	(B, 65)	(B, 400)
Dropout(p=0.2)	(B, 400)	(B, 400)
ReLU	(B, 400)	(B, 400)
Dense	(B, 400)	(B, 200)
Dropout(p=0.5)	(B, 200)	(B, 200)
ReLU	(B, 200)	(B, 200)
Dense	(B, 200)	(B, 4)
Softmax	(B, 4)	(B, 4)

#### Training dataset preparation:

- 1. Parameters were uniformly sampled from the following ranges:  $b_0 = [0;700]$ ,  $b_1 = [-40;40]$ ,  $p_0 = [0;600]$ ,  $p_1 = [-35;35]$ ,  $M_{22} = [-0.4;0.4]$ ,  $M_{11} = [-4;4]$ ,  $M_{12}^2 = [0;1.4]$
- 2. The signal was smeared by convolving with experimental LHCb resolution:

$$I(s) = \int_{m_{\psi} + m_p}^{m_{\Lambda_b} - m_K} I(s')_{\text{theo}} \exp\left[-\frac{(\sqrt{s} - \sqrt{s'})^2}{2R^2(s)}\right] d\sqrt{s'} / \int_{m_{\psi} + m_p}^{m_{\Lambda_b} - m_K} \exp\left[-\frac{(\sqrt{s} - \sqrt{s'})^2}{2R^2(s)}\right] d\sqrt{s'},$$

$$R(s) = 2.71 - 6.56 \times 10^{-6-1} \times \left(\sqrt{s} - 4567\right)^2$$

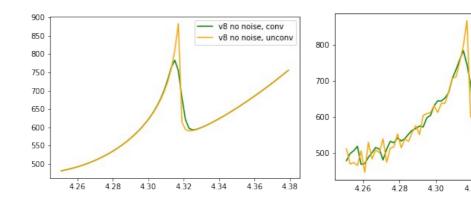

3.To account for experimental encertainty the 5% gaussian noise was added

#### ML model - training

 Input examples (efect of energy smearing and noise):

- Computing target classes:
  - m<sub>22</sub>>0 bound state, m<sub>22</sub><0 virtual state
  - To localize the poles on Riemann sheets we need to find zeros of the amplitude denominator in the momentum space:

$$p_0 + p_1 \, q + p_2 \, q^2 + p_3 \, q^3 + q^4 = 0$$
 with 
$$p_0 = (s_1 - s_2) \, m_{22}^2 - \left( m_{12}^2 - m_{11} m_{22} \right)^2$$
 
$$p_1 = 2 \, (s_1 - s_2) \, m_{22} + 2 m_{11} \, \left( m_{12}^2 - m_{11} m_{22} \right)$$
 
$$p_2 = -m_{11}^2 + m_{22}^2 + s_1 - s_2$$
 
$$p_3 = 2 m_{22}$$

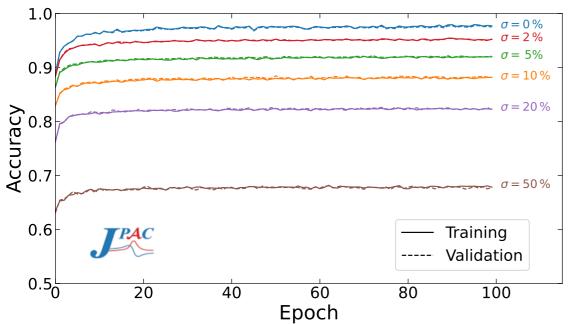

Then poles appear on sheets defined with  $(\eta_1, \eta_2)$  pairs:

(-,+) - II sheet 
$$\eta_1 = {\rm Sign} \ {\rm Re} \left( \frac{m_{12}^2}{m_{22}+q} - m_{11} \right) \ \eta_2 = {\rm Sign} \ {\rm Re} q$$

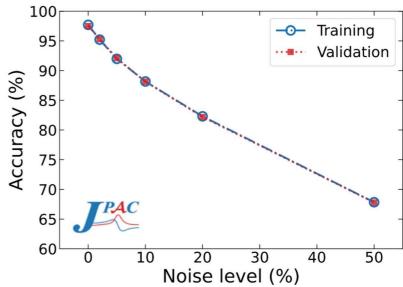

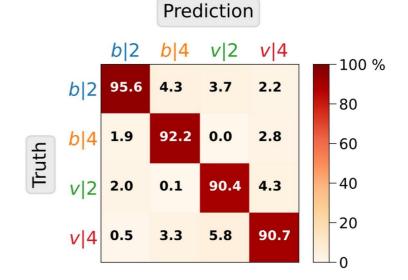

#### ML model – training results

#### Accuracy for various noise levels

Confusion matrix for the 5% noise

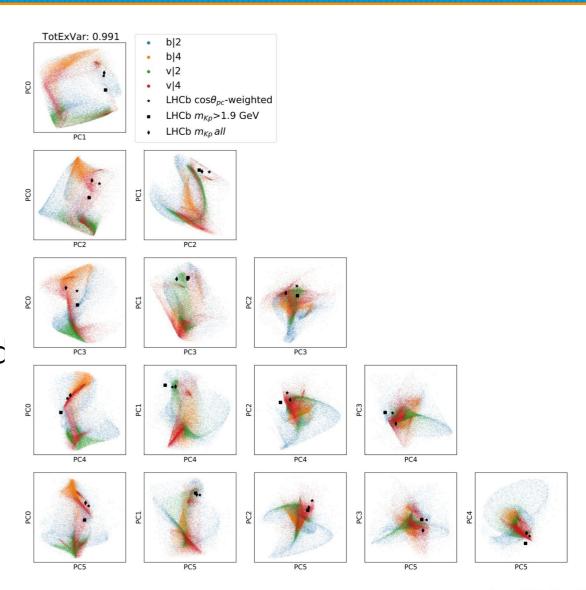

#### Feature refinement

- Dimensionality reduction -Principal Component analysis
- Over 99% of the variance can be explained with just 6 features
- Experimental data projected onto principal components are well encompassed within the training dataset

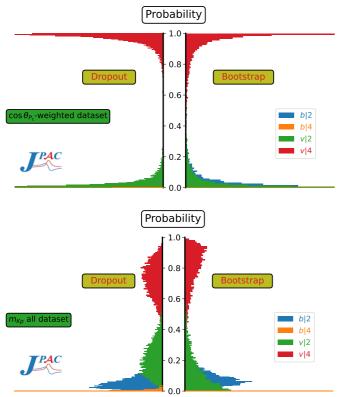

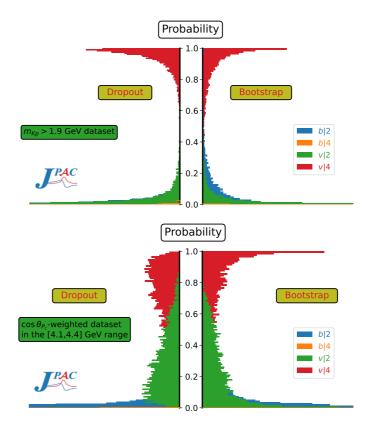

# Model predictions – statistical analysis

- The distribution of the target classes was evaluated with
  - the bootstrap (10 000 pseododata based on experimental mean values and uncertainties) and
  - dropout (10 000 predictions from the ML model with a fraction of weights randomly dropped out)

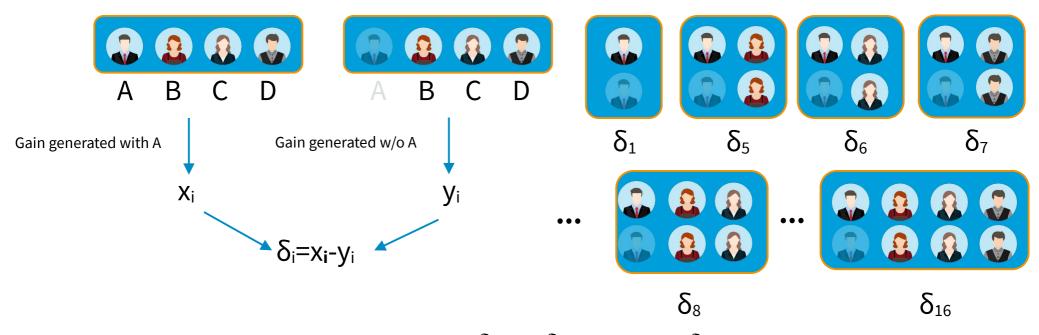

#### Model explanation with SHAP

Shapley values and Shapley Additive Explanations

Shapley, Lloyd S. "Notes on the n-Person Game -- II: The Value of an n-Person Game" (1951)

Shapley value for member A: 
$$\phi_A = \frac{\delta_1 + \delta_2 + \cdots + \delta_{16}}{16}$$

#### Model explanation with SHAP

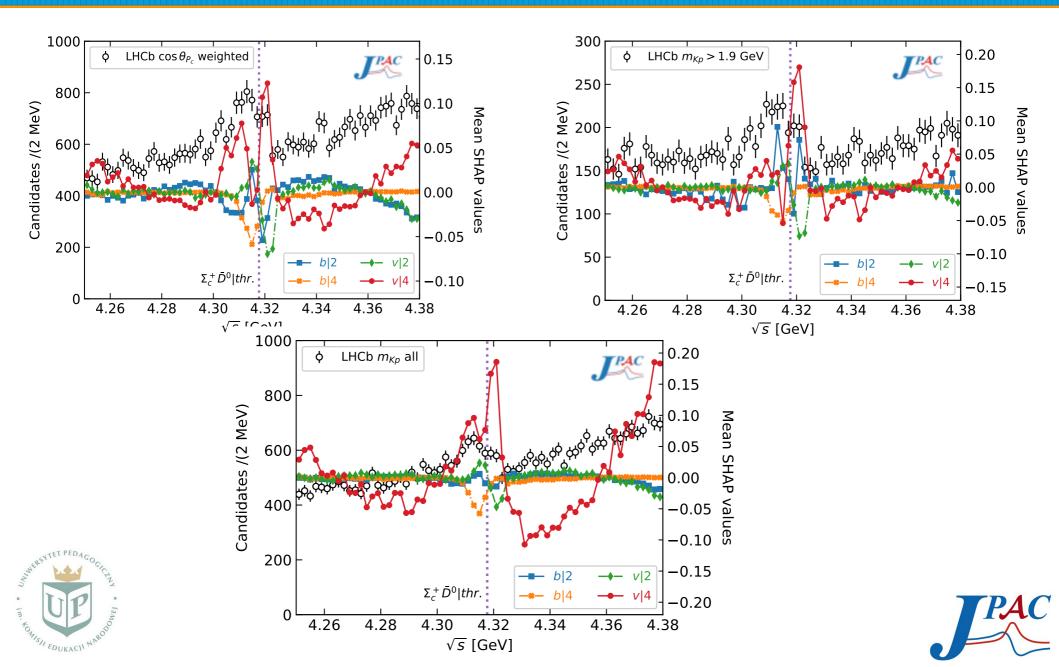

- By making an assotiation:
  - Member of a coalition → Feature (intensity in the energy bin)
  - Game → Function that generates classification/regression result
  - Gain → Prediction
  - We define the Shapley values for features
- Caveats:
  - A number of possible coalitions grows like 2<sup>N</sup>
  - Prohibitively expensive computationally (NP-hard)

Solution: Shapley additive explanations (Lundberg, Lee, arXiv:1705.07874v2, 2017)

#### Model explanation with SHAP

# Going beyond discriminative model (work in progress under A(I)DAPT collaboration)

#### Going beyond discriminative model

- Generative models learn to generate data instances drawn from pdf  $\rho(x_1,...,x_n)$ , which in turn is learnt from data
- Physically pdf-s are related to amplitudes of hadronic processes

$$\rho(x_1,...,x_n) \sim |A(x_1,...,x_n)|^2$$

- One can think about obtaining the amplitude from the pdf obtained from the generative model
- This problem is, unfortunately, ill posed problem
- Can additional conditions (unitarity, dispersion relations) cure the situation?

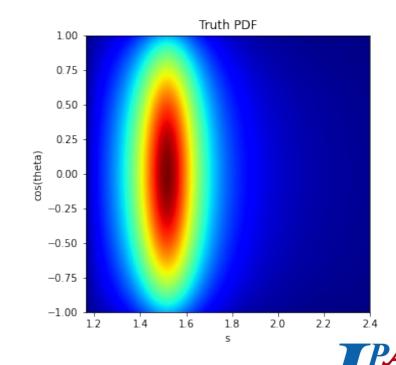

## π<sup>0</sup> photoproduction

• Consider the model for  $~\gamma p 
ightarrow p \pi^0$ 

$$\frac{d\sigma}{d\Omega} \propto \frac{p_f}{p_i s} \frac{3 \left| H_{3/2} \right|^2 + 5 \left| H_{1/2} \right|^2 - 3 \cos 2\theta \left( \left| H_{3/2} \right|^2 - \left| H_{1/2} \right|^2 \right)}{(m_{\Delta}^2 - s)^2 + \Gamma_{\Delta}^2 m_{\Delta}^2}$$

 Putting physical values of model parameters we obtain the 2d pdf in (s, cosθ) variables

## (Machine) Learning pdf-s

- Normalizing flows are the ML architectures designed to learn pdf-s from data
- Basic idea:
  - Let X and Z be n-dimensional random vectors and
  - $f: R^n \to R^n$  be the mapping between them so that X = f(Z) and  $Z = f^{-1}(X)$  (f must be invertible)
  - Then  $\rho_X(x) = \rho_Z(f^{-1}(x)) \left| \frac{\partial f^{-1}(x)}{\partial x} \right|$

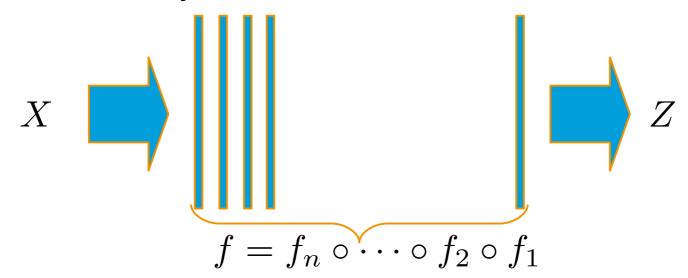

## (Machine) Learning pdf-s

#### In practice

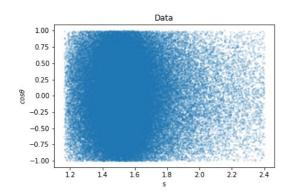

• f is implemented as a composition of several functions parametrized by neural network layers (flows) – activation functions must be invertible

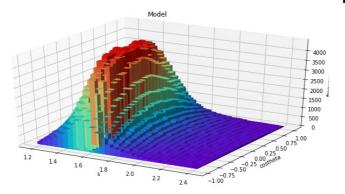

ullet is usually normal disributed, so we train the network to map unknown (either model or experimental) input distribution into a Gaussian noise

Having trained the network (to parametrize f ) we use it's invertibility to sample "unknown" distribution by feeding Gaussian noise.

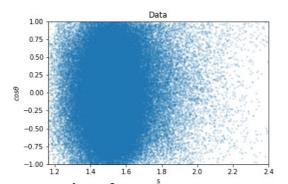

#### Results

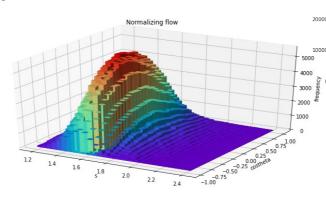

A sample of 10K events from the model distrubution

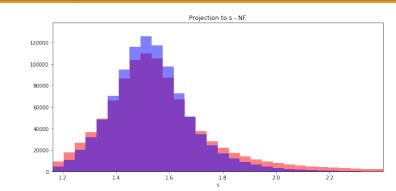

Histogrammed model sample

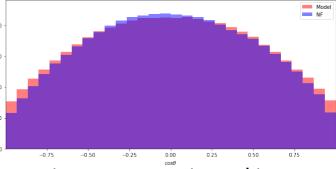

A sample of 10K events generated by the normalizing flow

Histogrammed normalizing flow sample

Projection to cosheta - N

- Histograms projected in s and in  $cos \theta$
- Some discrepancies visible but they can be reduced by hyperparameter fine-tuning
- This was an easy part obtaining the amplitudes requires imposing constraint of unitarity, eg. in the form of dispersion relations.
- It is still ahead of us.

#### Summary

- Classification of P<sub>c</sub>(4312) poles:
  - Rather than testing the single model hypothesis with  $\chi^2$ , we obtained the probabilities of four competitive pole assignments for the P<sub>c</sub>(4312) state
  - By the analysis of the SHAP values we obtained an ex post justification of our scattering length approximation
- Learning pdf-s (and possibly the amplitudes) with normalizing flows
  - With normalizing flows one can learn pdf-s from models (not a big deal) or experimental data(bigger deal)
  - Physical constraints of unitarity etc. have to be imposed on training in order to go from pdf-s to amplitudes.

#### Thank you!

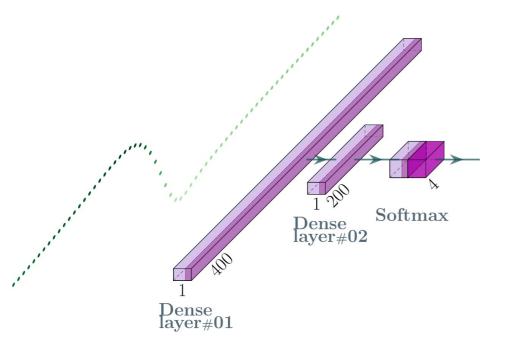

#### **Back-up slides**

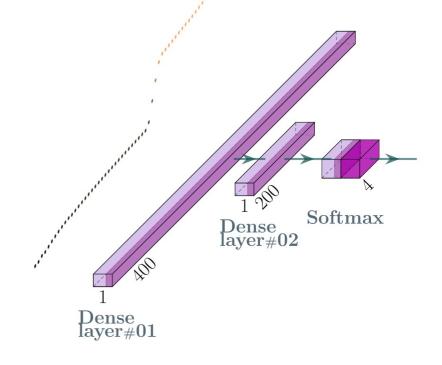

## Caveats (on using MLPs)

- Even though we want to recognize ordered sets (series) of data the MLP rather recognizes just sets
- One can permute the data arbitrarily and get basically the same classification quality
- Provided the prediction dataset is permuted accordingly

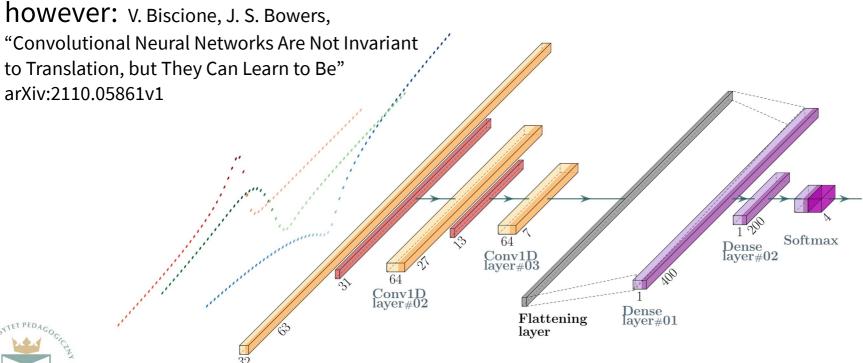

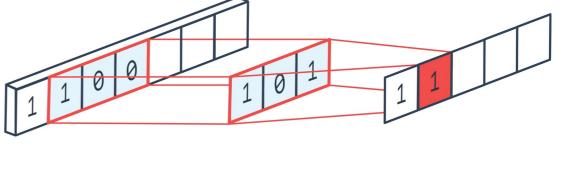

#### CNN as an alternative

- Convolution neural network is able to detect local patterns
- Unfortunately it does it in fixed location (it's not translationally invariant)
- There are some (partial) remedies

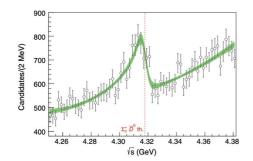

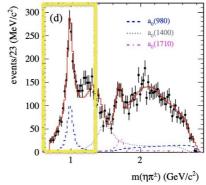

#### Questions to be addressed

• Going beyond the limited generalization power - applying the method for larger class of resonances, described by the same physics, eg. a<sub>0</sub>/f<sub>0</sub>(980) or other

resonances located near thresholds

- Eg. we believe that these two resonances can be described by the same physics
  - MLPs and CNNs require inputs of the same size rebinning required (but also kinematics and resonance parameters change: masses, widths, thresholds, phase spaces,...)
  - Alternatively we can use the length of the signal as part of the input information for RNNs
  - Difference between the models is not always as clear as above (different Riemann sheets) need for model selection criteria (discussed already on Wednesday)
