Re-Analysis of 3.5 keV line

Friday, 8 July 2022 17:40 (20 minutes)

I describe a reanalysis of data sets that have previously been found to harbor evidence for an unidentified X-ray line at 3.5 keV in order to quantify the robustness of earlier results that found significant evidence for a new X-ray line at this energy. The 3.5 keV line is intriguing in part because of possible connections to dark matter. We analyze observations from the XMM-Newton and Chandra telescopes. We investigate the robustness of the evidence for the 3.5 keV line to variations in the analysis framework and also to numerical error in the chi-square minimization process. For example, we consider narrowing the energy band for the analysis in order to minimize mismodeling effects. The results of our analyses indicate that many of the original 3.5 keV studies (i) did not have fully converged statistical analyses, and (ii) were subject to large systematic uncertainties from background mismodeling. Accounting for these issues we find no statistically significant evidence for a 3.5 keV line in any X-ray data set.

In-person participation

Yes

Primary authors: Prof. SAFDI, Benjamin (University of California, Berkeley); PARK, Yujin (University of California, Berkeley); DESSERT, Christopher (University of Michigan, Ann Arbor); Dr FOSTER, Joshua (MIT)

Presenter: PARK, Yujin (University of California, Berkeley)

Session Classification: Dark Matter

Track Classification: Dark Matter
