Direct CPV in charm hadrons at LHCb

Serena Maccolini

on behalf of the LHCb Collaboration

International Conference in HEP - July 7, 2022 **Bologna - Emilia Romagna, Italy**

serena.maccolini@cern.ch

TU Dortmund and Emmy Noether program

Why charm is charming?

- CP violation (CPV) in charm is suppressed (asymmetries expected ~0.1% or below)
 - Sensitive to possible contributions of physics beyond the SM
 - Up-type quark: <u>complementary</u> to studies in *K* and *B* systems

- $\sigma(pp \rightarrow c\overline{c} X)_{\sqrt{s} = 13 \text{ TeV}} \cong 2.4 \text{ mb}$
- LHCb is the main player in this quest
- [JHEP 03 (2016) 159]
- CPV in charm has been searched for since decades, in 2019 the LHCb experiment finally observed in neutral meson decays!

 Most promising channels are Cabibbo-suppressed (CS) decays because CPV may arise from the *interference* between the tree and the penguin amplitude

Time-dependent CP violation

In D⁰ mesons, the time-integrated CP asymmetry between the decay rates

$$A_{CP}(f) = \frac{\int \epsilon(t) \Gamma(D^0 \to f) dt - \int \epsilon(t) \Gamma(\overline{D}^0 \to \overline{f}) dt}{\int \epsilon(t) \Gamma(D^0 \to f) dt + \int \epsilon(t) \Gamma(\overline{D}^0 \to \overline{f}) dt}$$

doesn't correspond to a_f^d but is affected by $D^0 - \overline{D}^0$ mixing:

$$A_{CP}(f) \approx a_f^d + \frac{\langle t \rangle_f}{\tau_{D^0}} \Delta Y \qquad \Delta Y_f \approx -x_{12} \sin \phi_f^M + y_{12} \cos \phi_f^M a_f^d$$
[Phys. Rev. D 103, 053008]

where ΔY is related to the mixing parameters and $\langle t \rangle_f$ is the average (acceptance dependent) decay time of the D^0 mesons in the experimental sample. This corresponds to a correction of few times **10**-4.

[LHCB-PAPER-2022-024] in preparation

Measurement of direct *CP* asymmetries in $D^0 \rightarrow K^-K^+$ and $D^0 \rightarrow \pi^-\pi^+$ decays

<u>Presented</u> for the first time!

Motivation

• CP Violation in Charm has been observed in the difference

$$\Delta A_{CP} = A_{CP}(D^0 \rightarrow K^-K^+) - A_{CP}(D^0 \rightarrow \pi^-\pi^+)$$

= (-15.4 ± 2.9)x10⁻⁴

The measurement of $A_{CP}(D^0 \rightarrow K^-K^+)$ and $A_{CP}(D^0 \rightarrow \pi^-\pi^+)$ separately is necessary to understand the nature of CPV

- The <u>strategy</u> consists in measuring $A_{CP}(D^{O} \rightarrow K^{-}K^{+})$ and then retrieve a_{KK}^{d} and $a_{\pi\pi}^{d}$ from the combination with ΔA_{CP}
- Last measurement of $A_{CP}(D^0 \rightarrow K^-K^+)$ from LHCb using Run-1 data:

$$A_{CP}(D^0 \to K^+K^+) = [14 \pm 15 \text{ (stat)} \pm 10 \text{ (syst)}] \times 10^{-4}$$

[Phys. Lett. B 767 177-187]

Direct CPV measurements PV • D^{o} or \overline{D}^{o} tagging: $D^{*+-} \rightarrow D^{o} \pi^{+-}$ soft π^+ soft **prompt** (coming from primary vertex) • The *raw* asymmetry (A) in $D^{o} \rightarrow K^{-}K^{+}$ decays $A(D \to f) = \frac{N(D \to f) - N(D \to f)}{N(D \to f) + N(\bar{D} \to \bar{f})}$ includes both physics and detector effects: A_{CP}+(A_P)+(**NUISANCE ASYMMETRIES: Production** asymmetry **Detection** asymmetry **CPV** of **D***+ Of π^+ soft parameter $A_P(D) = \frac{\sigma(D) - \sigma(D)}{\sigma(D) + \sigma(\bar{D})} \quad A_D(f) = \frac{\epsilon(f) - \epsilon(f)}{\epsilon(f) + \epsilon(\bar{f})}$

Serena Maccolini

Direct CPV in charm

7 July 2022

$A(D \to f) = \frac{N(D \to f) - N(\bar{D} \to \bar{f})}{N(D \to f) + N(\bar{D} \to \bar{f})}$

Strategy

- Prompt $D^{\circ} \rightarrow K^{-}K^{+}$ collected during **Run-2**.
- Two methods to *cancel* **NUISANCE** asymmetries:
 - D+ decays, same used in Run-1 analysis (CD+)
 - **D**_s+ decays, new! (**C**_{Ds+})

particles with same color ("twin") must have identical kinematic distributions!

[backup]

 Correct raw asymmetry A using samples of Cabibbo-favoured D⁰/D_(s)+ decays (where CPV can be neglected):

$$\begin{aligned} \mathbf{C}_{D+}: \quad A_{CP}(D^0 \to K^- K^+) &= +A(D^{*+} \to (D^0 \to K^- K^+) \, \pi^+_{soft}) - A(D^{*+} \to (D^0 \to K^- \pi^+) \, \pi^+_{soft}) \\ &+ A(D^+ \to K^- \pi^+ \, \pi^+) - \left[A(D^+ \to \overline{K}^0 \, \pi^+) - A(\overline{K}^0)\right] \end{aligned}$$

$$\begin{aligned} \mathbf{C}_{DS+}: \quad A_{CP}(D^0 \to K^- K^+) &= +A(D^{*+} \to (D^0 \to K^- K^+) \, \pi^+_{soft}) - A(D^{*+} \to (D^0 \to K^- \pi^+) \, \pi^+_{soft}) \\ &+ A(D^+_s \to \phi \pi^+) - \left[A(D^+_s \to \overline{K}^0 \, K^+) - A(\overline{K}^0)\right] \end{aligned}$$

where $A(\overline{K}^0)$ includes the detection asymmetry of *neutral kaons*, mixing and *CP*-violating effects.

• For each *kinematically weighted* sample, the raw asymmetry A is determined with a *simultaneous* fit to the *positive* and *negative* final state invariant-mass distributions

Direct CPV in charm

7 July 2022

Final results for A_{CP}(K⁻K⁺) and combination

• Final results for $A_{CP}(K^{-}K^{+})$ are:

C_{D⁺}: $\mathcal{A}_{CP}(K^{-}K^{+}) = [13.6 \pm 8.8 \,(\text{stat}) \pm 1.6 \,(\text{syst})] \times 10^{-4},$ C_{D⁺}: $\mathcal{A}_{CP}(K^{-}K^{+}) = [2.8 \pm 6.7 \,(\text{stat}) \pm 2.0 \,(\text{syst})] \times 10^{-4}.$

with an overall correlation coefficient $\rho = 0.06$ and are found to be compatible within 1 standard deviation.

• The combination yields

 $\mathcal{A}_{CP}(K^{-}K^{+}) = [6.8 \pm 5.4 \,(\text{stat}) \pm 1.6 \,(\text{syst})] \times 10^{-4},$

 $\Delta Y = [-1.04 \pm 1.17] \times 10^{-4}$
[Phys. Rev. D 104, 072010]

• **Direct CP violation parameters** a_{KK}^d and $a_{\pi\pi}^d$ in $D^0 \rightarrow K^-K^+$ and $D^0 \rightarrow \pi^-\pi^+$ are calculated from the **combination** of $A_{CP}(K^-K^+)$ with ΔA_{CP} and accounting for possible *timedependent CP* violation considering

$$A_{CP}(K^{-}K^{+}) = a_{KK}^{d} + \frac{\langle t \rangle_{KK}}{\tau_{D^{0}}} \Delta Y$$
$$\Delta A_{CP} = a_{KK}^{d} - a_{\pi\pi}^{d} + \frac{\langle t \rangle_{KK} - \langle t \rangle_{\pi\pi}}{\tau_{D^{0}}} \Delta Y$$

• All Run-1 and Run-2 measurements are embedded in a **global** χ^2 , taking into account *correlations*.

First evidence for direct CP violation

$$a_{K^-K^+}^d = (7.7 \pm 5.7) \times 10^{-4} = (23.2 \pm 6.1) \times 10^{-4}$$

$$a_{\pi^-\pi^+}^d = (23.2 \pm 6.1) \times 10^{-4} = (23.2 \pm 6.1) \times 10^{-4}$$

$$a_{\pi^-\pi^+}^d = (23.2 \pm 6.1) \times 10^{-4} =$$

• They report the <u>first evidence</u> for **direct CP violation** in $D^0 \rightarrow \pi^-\pi^+$ decays at the level of **3.8** σ .

• *U-spin* breaking in CP asymmetries:
$$a_{KK}^d + a_{\pi\pi}^d \neq 0$$
 at the level of 2.7 σ .

Conclusions

- A measurement of $A_{CP}(D^{O} \rightarrow K^{-}K^{+})$, using *prompt* decays collected during *Run-2*, has been presented
- A precision of 6x10-4 has been obtained combining D+ and D_s+ decays to cancel nuisance asymmetries.
- The measurement is the most accurate in the **world** and is still statistically dominated.

• Direct *CP* violation asymmetries a_{KK}^d and $a_{\pi\pi}^d$ are calculated from the combination of A_{CP} with previous LHCb measurements, revealing the **first evidence** for direct *CP* violation in $D^0 \rightarrow \pi^-\pi^+$ decays

Thanks!

Serena Maccolini

*D*⁰→*K*-*K*+ processes (as an example)

- For simplicity, the $D^0 \rightarrow K^-\pi^+$ sample is **split in 2** subsamples to be used in the D^+ and D_{s^+} methods.
- D^{*}+/D_(s)+ meson has to be *prompt* to avoid production asymmetries from B meson decays → cut on the impact parameter (IP)
- *Kinematic regions* with very large values of *raw asymmetries* need to be **removed**
- Tight particle-ID cuts to reduce **mis-ID** backgrounds
- The "harmonization" rule: every kinematic, PID and trigger requirement applied to a
 particle must be applied to the other "twin" particle. This simplifies the weighting
 procedure and avoids any possible final-state induced asymmetries.

The "harmonization" rule

 In the formula, "twin" particles must induce the exact amount of nuisance asymmetry

$$\mathbf{C}_{D+}: A_{CP}(D^{0} \to K^{-}K^{+}) = +A(D^{*+} \to (D^{0} \to K^{-}K^{+})\pi_{soft}^{+}) - A(D^{*+} \to (D^{0} \to K^{-}\pi^{+})\pi_{soft}^{+}) + A(D^{+} \to K^{-}\pi^{+}\pi^{+}) - \left[A(D^{+} \to \overline{K}^{0}\pi^{+}) - A(\overline{K}^{0})\right]$$

$$\begin{aligned} \mathbf{C}_{DS+}: \ A_{CP}(D^0 \to K^- K^+) &= +A(D^{*+} \to (D^0 \to K^- K^+) \, \pi^+_{soft}) - A(D^{*+} \to (D^0 \to K^- \pi^+) \, \pi^+_{soft}) \\ &+ A(D^+_s \to \phi \pi^+) - \left[A(D^+_s \to \overline{K}^0 \, K^+) - A(\overline{K}^0)\right] \end{aligned}$$

- Every kinematic, PID and trigger requirement applied to a particle must be applied to the other "twin" particle
- This simplifies the *weighting* procedure and avoids any possible final-state induced asymmetries

Weighting procedure

- For each method, an *iterative* weighting approach has been used on the *four* decay modes.
- This is done until a satisfactory agreement of all kinematic distributions is obtained.

Serena Maccolini

Fit results

Neutral kaon asymmetry

- Different interaction cross-sections of K^0 and \overline{K}^0 mesons with matter, including effects due to mixing and CPV induce and $0.1 \ 0.2 \ 0.3 \ 0.4 \ 0.4 \ 0.4$ asymmetry.
- Evaluated for each sample with a K_S in the final state using LHCb material map from simulation (Si,Al,vacuum), neutralkaon cross-sections, forward scattering phase, mixing and CPV.

Validation with MC and consistency

The weighting procedure is ve assumptions embedded in the asymmetries for A_{CP} using hug samples.

 Several consistency checks to verify that A_{CP}(K-K+) does not depend on running conditions, kinematics, topology, PID and high-level trigger selection.
